(54) Title: **BATTERIES INCLUDING A FLAT PLATE DESIGN**

(57) Abstract: A battery having flat, stacked, anode and cathode layers. The battery can be adapted to fit within an implantable medical device.

**BEST AVAILABLE COPY**

## BATTERIES INCLUDING A FLAT PLATE DESIGN

### Related Application

This application claims the benefit under 35 U.S.C. 119(e) of U.S. Provisional Application Serial Number 60/437,537 filed December 31, 2002, the specification of which is hereby incorporated by reference.

5

### Technical Field

The present invention concerns implantable medical devices, such as defibrillators and cardioverters, and more specifically to a battery for such devices.

### Background

10

Patients prone to irregular heart rhythms sometimes have miniature heart devices, such as defibrillators and cardioverters, implanted in their bodies.

These devices detect onset of abnormal heart rhythms and apply corrective electrical therapy to the heart. The defibrillator or cardioverter includes a set of electrical leads, which extend from a device housing into the heart. Within the device housing are a battery for supplying power, circuitry for detecting abnormal heart rhythms, and a capacitor for delivering bursts of electric current through the leads to the heart. Since defibrillators and cardioverters are typically implanted in the left region of the chest or in the abdomen, a smaller size device, which is still capable of delivering the required level of electrical energy, is

15

20

desirable.

The basic components that make up a battery are an anode, a cathode, a separator between the anode and the cathode, electrolyte, and packaging hardware such as the case. Batteries can be of a wound, jellyroll, style of design that may be cylindrical or flattened cylindrical in shape. Some designs fold the battery components on top of one another.

25

The anodes and cathodes of the battery are opposed to each other throughout the battery. This continuous opposition requirement creates packaging inefficiencies, such as wasted volume at bend lines or, in the wound

configuration, the mandrel volume itself. Moreover, these folded or wound design approaches are limited to simple cross-sectional areas due to the manufacturing constraints of producing such a battery cell. It is desirable to improve the packaging efficiency of the battery particularly for medical implantable devices, since this will provide a smaller battery. Also, consistency from one battery to the next is a desirable feature for implantable medical devices. A heightened consistency allows the battery's life-cycle to be predictable and allows the battery to be replaced at an opportune time without emergency.

#### **Description of Embodiments**

- In the following detailed description, reference is made to the
- 20 accompanying drawings which form a part hereof, and in which is shown by way of illustration specific embodiments in which the invention may be practiced. These embodiments are described in sufficient detail to enable those skilled in the art to practice the invention, and it is to be understood that other embodiments may be utilized and that structural changes may be made without
- 25 departing from the scope of the present invention. Therefore, the following detailed description is not to be taken in a limiting sense, and the scope of the present invention is defined by the appended claims and their equivalents.

- Figure 1 shows an exploded view of a battery 18 according to one embodiment. The present embodiment shows a D-shaped battery. In other
- 30 embodiments, battery 18 can be designed in a variety of flat shapes to conform to various housing shapes. The discussion herein provides techniques to manufacture a battery having virtually any arbitrary shape, such as rectangular or

non-rectangular. Moreover, the edges of the battery can be curved to allow the battery to fit in a shape-friendly curved case, as will be detailed below. The battery includes a metallic case 20 defining a chamber 22 which holds a battery stack 24. In one embodiment, case 20 is manufactured from a conductive  
5 material, such as stainless steel. In another option, the case 20 is manufactured using a nonconductive material, such as a ceramic or a plastic.

Case 20 includes a base 26 and a lid 28 positionable on an upper rim 27 of base 26. Battery stack 24 has a cutout region 34 at its periphery, with cutout region 34 being positioned when the stack 24 is installed in case 20 to provide  
10 space for electrical connections. A feedthrough post 36 passes through lid 28 to stack 24 and is electrically insulated from case 20 and lid 28. Feedthrough post 36 is connected to a cathode tab 35, while an anode tab 37 is directly attached between lid 28 and base 26 such that the case itself acts as the anode terminal. In some embodiments, these roles are reversed and the cathode tab is connected to  
15 the case and the anode tab connects to a feedthrough. In some embodiments, two feedthroughs are provided, one for the anode and one for the cathode. Battery stack 24 is covered with insulating member 38 when mounted within case 20. Other embodiments of insulating members, such as member 38, will be discussed below. In one embodiment, a backfill port 43 is located in the battery  
20 case. A backfill plug 41 and an optional cover 45 seal the backfill port after the battery case is filled with electrolyte.

Battery stack 24 is constructed to provide optimal power storage in a small space and allows for a battery having almost any arbitrary shape or form factor. This allows battery 18 to be designed and dimensioned to fit within an  
25 implantable medical device, for example, and take up as little volume within the device as possible. In one embodiment, stack 24 includes a plurality of alternating anode and cathode layers separated by separators. As will be detailed below, these alternating electrode layers are stacked, aligned, and interconnected to allow for maximal electrode area in a minimal volume with minimal wasted  
30 space. For example, in one embodiment, battery 18 includes a layered stack of electrodes where the interconnections between layers are spread out so as to minimize the interconnection volume.

Figure 2 illustrates an exploded view of battery stack 24 according to one embodiment. Battery stack 24 includes an anode assembly including a plurality of anode sub-assemblies 100-100D and a cathode assembly including a plurality of cathode sub-assemblies 300-300D, with separator layers 200 interposed  
5 between each of the sub-assembly layers. This flat, stacked, layered structure omits the wasted mandrel volume of wound batteries and the wasted edge fold volume of folded batteries. Moreover, the flat, discrete layers allow the battery designer to make the stack almost any shape desirable. This allows a medical device designer to choose a battery which can accommodate a given space within  
10 the medical device.

One anode sub-assembly is a base, manifold anode collector layer 100 which includes one or more tabs (A-E) extending from an edge of the anode layer body. Other anode sub-assembly layers in stack 24 include secondary anode collectors 100A-100D, which each include an extension tab, designated  
15 A-D, respectively. In this example, secondary anode sub-assembly collectors 100A each have a tab A which overlays and is aligned with base anode layer 100's tab A. In a likewise manner, secondary anode sub-assembly collectors 100B-100D each include an extension tab (B-D, respectively) which vertically matches or overlays and aligns upon base layer 100 tabs B-D respectively. In  
20 this embodiment, base layer 100 tab E includes tab 37 which connects the anode assembly to the battery case (Figure 1). By spreading the anode interconnections to base layer 100 out over four separate areas, the overall thickness required by the interconnections is lessened and less space is needed between stack 24 and case 20 (Figure 1).

25 The cathode assembly of battery 24 includes a base, manifold cathode collector layer 300 which includes one or more tabs (A-D) extending from an edge of the cathode layer body. Other cathode sub-assembly layers in stack 24 include secondary cathode collectors 300A-300D, which each include an extension tab, designated A-D, respectively. In this example, secondary cathode  
30 sub-assembly collectors 300A each have a tab A which overlays and is aligned with base cathode layer 300's tab A. In a likewise manner, secondary cathode sub-assembly collectors 300B-300D each include an extension tab (B-D,

respectively) which overlies and aligns upon base layer 300 tabs B-D respectively. In this embodiment, base layer 300 includes tab 35 which connects the cathode assembly to feedthrough 36 (Figure 1). Again, by spreading the cathode interconnections to base layer 300 out over four separate areas, the overall thickness required by the interconnections is lessened and less space is needed between stack 24 and case 20 (Figure 1).

Each separator 200 separates an anode sub-assembly 100-100D from a cathode sub-assembly 300-300D. Each separator 200 includes a first edge 251, a clearance area defined by a second edge 252, and a flat edge 253. The clearance area of separator 200 allows for interconnections to the feedthrough. Separator 200 is, in one option, made from a roll or sheet of separator material. Suitable materials for the separator material include, but are not limited to, a polyethylene, such as Tonen™, or a trilayer (polypropylene, polyethylene, polypropylene) separator material such as Celgard™ 2325, for example. Other chemically inert materials are suitable as well, such as porous polymeric materials. In one embodiment, each separator layer 200 is cut slightly larger than the anode layers (or cathode layers) to accommodate misalignment during the stacking of layers, to prevent subsequent shorting between electrodes of opposite polarity, and to act as an outermost edge for alignment.

Figures 3-8 show further details of an anode assembly of stack 24 according to one embodiment. Figure 3 shows an anode material 110. In this example anode 110 is a lithium (Li) anode. Each anode sub-assembly 100-100D includes either one or two anodes 110 on the major surfaces of the sub-assembly. In various embodiments, the anode material 110 can be pressed into a mesh or etched base layer, or onto the surface of a base layer, or be of pure Lithium and have no base layer. In one example, a sheet of Lithium is attached to a base layer and then die cut to the desired shape.

Figure 4A shows base manifold anode collector layer 100. Collector layer 100 includes an outer edge 130, a cut-out 132, an upper flat edge 134, and an edge 136. The base layer 100 also includes extension tabs A-E. In one embodiment, each extension tab A-E is integral to layer 100. Some embodiments attach separate tabs A-E to layer 100. Figure 4B shows a detail of

base layer 100. In one embodiment, layer 100 is formed of a main body 120 including a stainless steel material, such as 316L SST, or a nickel material. A plurality of holes 125 are optionally incorporated into the stainless steel material. One or two anodes 110 (Figure 3) are attached to the major surfaces of body 120. Tabs A-E (Figure 4A) are not covered with anode material. In one embodiment, the anodes can be formed by attaching strips of Lithium to one or both sides of strips of stainless steel, leaving an edge open along a portion of the stainless steel strip for the tabs. One or more anode parts of desired shape are then excised from the strip.

Figures 5-8 show anode sub-assemblies 100A-100D. Each of these secondary anode layers includes an outer edge 130, a cut-out 132, an upper flat edge 134, and an edge 136 designated by the corresponding letters A-D in the respective Figures. Each layer also includes a tab 140A-140D, respectively, with the tab of each separate layer being offset from the previous and subsequent layers.

Figures 9-14 show further details of a cathode assembly according to one embodiment. Figure 9 shows an exploded view of a cathode sub-assembly having a metal collector sheet 301 and a cathode material 310 on one major surface and a cathode material 312 on a second major surface. In one embodiment, cathodes 310 and 312 are  $\text{MnO}_2$  (manganese dioxide). One mix ratio is about 90%  $\text{MnO}_2$ , 5% PTFE, and 5% carbon. Another embodiment provides a mix ratio of 90%  $\text{MnO}_2$ , 5% binder, and 5% carbon or graphite. In one example, the cathode material can be a powder which is pressed into a mesh base layer. In one embodiment, a cathode paste can be provided which can be laminated, pressed, rolled, or otherwise mounted onto the surface of a base layer, as will be detailed below. In various examples, the cathode material can be a powder, paste, or adhered slurry.

Figure 10 shows base manifold cathode collector 300. Collector 300 includes an outer edge 330, cut-out 332 having tab 35 therein, and upper flat edge 334. Collector layer 300 also includes four extension tabs A-D.

Figure 11A shows cathode sub-assembly secondary layer 300A having outer edge 330A, cut-out 332A, and flat edge 334A. A tab 340A extends from

edge 334A. Figure 11B shows a detail of collector 300A. In this embodiment, collector 300A is formed of a main body 320 including a stainless steel sheet. A plurality of diamond structures 305 are incorporated into the main body by etching, an expanded metal process, by a mechanical process, or by laser, for example. One or two cathodes 310 and 312 (Figure 9) are attached to the major surfaces of body 320. Tab 340A is not covered with cathode material. In one embodiment of forming the cathodes, a layer of a paste or slurry is applied to one or both sides of a stainless steel base layer, the strip is rolled or pressed to meter and attach the cathode material to the base layer, and then one or more cathodes are excised from the strip. In one example, the cathode layer is applied leaving the cathode tabs bare.

Figures 12-14 show secondary cathode sub-assembly layers 300B-300D, respectively. Each secondary cathode layer includes an outer edge 330, cut-out 332 and upper flat edge 334 shown by the corresponding letters B-D in the respective Figures. Each layer also includes a tab 340B-340D, respectively, with the tab of each separate layer being offset from the previous and subsequent layers.

Again, each anode tab 140A-140D and each cathode tab 340A-340D corresponds to a tab A-D on either the base anode layer 100 or the base cathode layer 300.

Also, these spread out interconnections of the anodes and cathodes decrease the overall thickness of the space between the stack and the case, allowing for a smaller battery size. To ensure that a battery stack takes up as little volume as possible and to optimize the consistency between each battery being manufactured, it is important to carefully align each layer of the battery stack when constructing the stack. In one embodiment, battery stack 24 described above is aligned using an alignment fixture to provide for optimal surface area of the battery.

Figure 15 illustrates an alignment mechanism or fixture 400 used to assemble battery stack 24, in accordance with one embodiment. Alignment mechanism 400 includes a plurality of precisely placed alignment elements 501-504. Alignment elements 501-504 are vertically oriented alignment elements

which extend from a base 402. Base 402 supports battery components thereon, while the alignment elements 501-504 align the battery layers while the layers are being stacked therein.

Figures 16-17 shows one example use of alignment fixture 400. Figure 5 16 shows a perspective view of stack 24 within the fixture and Figure 17 illustrates a top view of battery stack 24 within fixture 400. Battery stack 24 includes a plurality of discrete electrode layers with each layer aligned relative to the position of the alignment elements 501-504. A channel can be provided in base 402 to hold a fastener for wrapping around a portion of the battery stack 24 10 once it has been stacked and aligned. In one example, a tool can be inserted into the channel to clamp the stack and remove it for taping. Precise alignment of battery stack 24 is maintained by the alignment elements 501-504 when wrapping the battery stack 24.

In one example, to align the layers of battery stack 24, a separator layer 15 200 is attached to each respective electrode layer of the stack. The separators 200 can be dimensioned such that they slightly overhang the edges of each electrode layer. Each layer is then placed between alignment elements 501-504. One or more points on the outer perimeter edges (251-253, etc.) of each separator layer abut against each of the elements 501-504, precisely aligning that layer. This 20 technique helps to reduce variances in alignment which may result from varying tolerance stack ups between layers of the assembly and the alignment fixture used. Moreover, by using the outer edges, no area within the body of each layer is wasted by using alignment holes, for example.

In one embodiment, each separator layer 200 is aligned relative to the 25 plurality of alignment elements 501-504 by placing the separator so that outer edge 251 and edge 253 extend to contact the alignment elements 501, 502, 503, and 504. In one example, the separator layer 200 is then attached to an anode assembly 100-100D or a cathode assembly 300-300D while the separator is positioned within the fixture. These sub-assembly layers are then put one by one 30 into fixture 400 between elements 501-504. The edges of the separators 200 contact the elements 501-504 and align the electrode layers.

In one embodiment, each sub-layer or series of sub-layers are pressed to help reduce warpage and thus to reduce the overall height of the battery stack 24. A fastener 351 (Figure 21) can be wrapped around a portion of the stack 24 to retain the alignment of the layers relative to one another. In one embodiment,  
5 the fastener includes a tape that is wrapped around a central portion of the battery stack 24. The battery stack 24 can then be clamped and annealed.

In some embodiments, the anode sub-assembly layers 100-100D and the cathode sub-assembly layers 300-300D are aligned relative to one another within case 20, instead of using the external alignment mechanism 400, and then are  
10 coupled to one another in the aligned position. For instance, an outer edge of a separator of the anode sub-assembly and an outer edge of a separator of a cathode sub-assembly can contact an interior surface of the case 20, and would be aligned therein.

Among other advantages, use of the alignment fixture described above  
15 provides for a battery making efficient use of space within the case, permits increased anodic and cathodic surface area, and increased capacity for a battery of a given set of dimensions. Variation in the outer dimensions of one battery stack 24 to another battery stack 24 is reduced because each is formed within alignment elements positioned the same manner. Moreover, dimensional  
20 variations in the battery stack resulting from variation in the reference points from case to case or alignment apparatus to alignment apparatus are eliminated. This provides improved dimensional consistency in production and allows for reduced tolerances between the battery stack and the battery case. This allows for more efficient use of space internal to the battery case.

25 Furthermore, multiple points can be used to make the alignment, reducing the effect of the tolerance stack up between the conductive layer or separator being aligned and the alignment element at any one position. This also facilitates for alignment of components which during certain steps in the manufacturing process have portions which extend beyond the dimensions  
30 defined by the case and are later formed to fit within the case.

The battery stack structure described above provides for greater cathodic/anodic surface area since, by aligning to the separator, the

cathode/anode surface area is optimized by not having to provide extraneous alignment notches or other alignment features within or on the electrodes themselves which decrease the electrode surface area. However, in some embodiments, one or more features, such as holes or notches can be provided in the surface of each of cathode assembly 300-300D, anode assemblies 100-100D, and separators 200 allowing for internal alignment of the stack. For example, fixture 400 can include a central post and each layer is mounted over the central post such that each layer is registered.

Figure 18A shows a sectional side view of an alignment mechanism 600 for forming a battery stack according to one embodiment. Alignment mechanism 600 generally includes a base 610, a base pad 620, and first and second upper members 634 and 636. In use, fixture 600 helps to continually keep all the layers of a battery stack 624 in compression as the battery stack is being formed. In one embodiment, as will be detailed below, as each separate layer of the battery stack is placed upon base pad 620, the base pad urges the stack upward while upper members 634 and 636 provide a holding, downward force on the stack such that the stack is squeezed between base pad 620 and upper members 634 and 636. This squeezing or compression holds each layer of the battery stack in the position in which it was placed on the stack, thus keeping the alignment of the battery stack.

Base 610 includes an interior cavity 640. In one embodiment, interior cavity 640 is shaped to accommodate base pad 620 therein to allow the base pad to translate up and down. Base pad 620 and cavity 640 are shaped to accommodate example battery stack 624. As noted above, flat batteries can be formed into almost any shape. Accordingly, base pad 620 can have almost any shape.

Base pad 620 includes a flat top surface for supporting a bottom surface of battery stack 624. In one embodiment, the surface area of the base pad surface is slightly larger than the surface area of the battery stack. In one embodiment, a straight, longitudinal groove 627 is provided in the top surface of base pad 620. Along with a corresponding groove in base pad 610, groove 627 provides a space for a binder such as a tape to be laid into while a battery stack is being

formed in fixture 600. After the stack is formed, the tape can be wrapped around the battery stack to bind the stack and to hold the stack's alignment. Groove 627 can also be used as a stack picking feature. For example, a tool can be inserted into the channel of groove 627 to clamp the stack and remove it for taping.

5 Some embodiments omit groove 627.

Fixture 600 includes one or more forcing or biasing members such as springs 626 which are located beneath base pad 620 to urge base pad 620 upward. In use, the spring force grows as the stack is formed until the force is approximately 2 lbs. when the base pad is fully depressed. In other examples,  
10 the high end force can range from 1/4 lb. to approximately 3 lbs., approximately 4 lbs., or more, depending on the material being stacked. Also, the low-end force (i.e., when the stack is empty) can be varied. For example, a pre-load can be applied on the springs to urge the base pad against the bottom of members 634 and 636 before any battery layers have been placed therein. This pre-load  
15 force can range from zero, less than approximately 1/4 lb to approximately 1/4 lb., approximately 1/2 lb., or more, depending on the application. In one embodiment, the spring is omitted and a pressurized air dashpot mechanism is located under base pad 620 to urge the base pad upward. The pressurized air mechanism can have adjustable air pressure settings, and allow for a constant  
20 upward force on the base pad.

In one embodiment, each upper member 634 and 636 is a thin, flat member, such as a metal strip or a plastic strip. In this example, the upper members 634 and 636 are located so as to contact the top side edges of the battery stack when the stack is being formed. This helps keep the edges of a  
25 given layer from curling up. This helps prevent misalignment of the stack since any deviation from flatness can be a cause of misalignment.

In one example use, a robotically controlled vacuum placement arm 660 places each new layer 624X on top of the previous layer. Some embodiments provide manual placement of each layer. A vision alignment system can be used  
30 to align the layers. Upper members 634 and 636 are movably attached to the fixture so that they can rotate off and on the stack. For example, uppers members 634 and 636 are moved out of the way when a new layer is being place

on the stack and arm 660 holds the stack in compression. After the new layer is placed correctly the members 634 and 636 move back over the edges of the top of the stack and the arm 660 is removed and the arms then hold the stack in compression. This process is then repeated until the stack is formed.

5        Fixture 600 allows for precise alignment of a battery stack which has a curved or non-uniform profile (See Figures 21 and 22 for example, where the upper and lower portions of stack 24 are smaller in area than the middle portion, resulting in a curved profile battery stack). In such a curved profile battery stack, the edges are not uniform so as to provide precise alignment when stacking in a  
10       fixture such as fixture 400. However, by squeezing the stack, fixture 600 allows for precise alignment regardless of the edge profile of the stack.

      Further details of some embodiments of alignment mechanism 600 are discussed in co-pending and co-assigned U.S. Application 10/050598 (filed 1/15/2002) entitled METHOD OF CONSTRUCTING A CAPACITOR STACK  
15       FOR A FLAT CAPACITOR, which is incorporated herein by reference in its entirety.

      Figures 18B-18F show a stacking fixture 670 according to one embodiment. Stacking fixture 670 includes some similar features as discussed above for fixture 600 and certain details will be omitted for sake of brevity.  
20       Fixture 670 includes a base 672 to hold a stack as the stack is being built layer by layer. One embodiment includes springs or other forcing members (such as an air pressure dashpot mechanism, as discussed above) under base 672 to urge the base and the battery stack upwards (as discussed above for fixture 600). Fixture 670 includes a placement member 671B to deliver each anode, cathode, or  
25       separator layer to the stack. In some embodiments, placement member 671B can include manual placement members, vacuum placement members, robotically controlled placement members, vision alignment systems and so on as discussed above. In one embodiment, an upper clamping member 671A is rotatably coupled to fixture 670 to apply top pressure on the stack when upper members  
30       673 and 674 are moved away and placement member 671B is moved away. Other embodiments omit member 671A and utilize the technique described below. A groove or channel can be provided in the upper portion of the base 672

to allow for a tape strip or a tool to be inserted to remove the stack from the fixture.

Fixture 670 includes upper members 673 and 674 which are situated on opposite sides of the stack. Each upper member 673 and 674 includes a  
5 contacting member 675 and 676, respectively. Each of the contacting members 675 and 676 is held in tension and supported by being mounted to arms 680 and 681 at each of the contacting members ends. Contacting members 675 and 676 contact the top surface of the top layer of the battery stack as it is being built. The compression or holding force between the contact members 675 and 676 and  
10 the base pad 672 keeps the battery stack in alignment as the stack is being built layer by layer.

Figure 18C shows a view of contacting members extending across a top surface of a top layer 677 of a battery stack 678. It is noted that the battery stack can be oriented in any manner desirable (e.g. the stack can be turned 90 degrees  
15 relative to Figure 18C). Figure 18D shows one embodiment of a contacting member 675B. Contacting member 675B includes a thin strip of plastic, such as a mylar, polyethelyne, or polypropylene film web, for example. Various embodiments have contacting members having a thickness of approximately 0.001 inches or less, to approximately 0.005 inches. This end-supported thin  
20 web of material is stronger and better supported than a cantilevered member and the thinness of the material allows for a minimal deflection of each new layer as it is put on top of the stack.

Figure 18E show a contacting member 675C which includes a roll of thin plastic material. In this example, the web of member 675C can be indexed and  
25 drawn through arms 680 and 681 every one or more times it is used. This can provide clean material for contacting the battery stack and allow the web to maintain its strength.

Figure 18F shows an example use of fixture 670 in placing top layer 677 onto a battery stack 678. In this example each layer of the battery stack is  
30 aligned and placed upon the stack which rests on base pad 672. Only contacting member 675 is shown in Figure 18F for sake of clarity. In one embodiment,

second contacting member 676 is used on the opposite side of the stack as shown in Figure 18B.

In use, placement member 671B places layer 677 on top of the stack and holds the layer as originally aligned in place on top of the stack. In such a position the edge of layer 677 is then on top of contacting member 675. Contacting member 675 is then moved outward to position 1, upward to position 2 then back to positions 3 and 4 where the bottom of contacting member 675 then contacts and holds layer 677 down upon stack 678. Placement member 671B then moves away to get the next layer with contacting member 675 (and 676) holding the stack in alignment. This process is then continued until the battery stack is formed, with member 671B and members 675 and 676 alternately keeping the stack in compression.

As with fixture 600, fixture 670 allows for precise alignment of a battery stack which has a curved or non-uniform profile (See Figures 21 and 22). In such a stack, the edges are not uniform so as to provide precise alignment when stacking in a fixture such as fixture 400. However, by squeezing or at least holding the stack still, fixture 670 allows for precise alignment regardless of the edge profile of the stack since the stack never has the opportunity to shift once a layer is aligned and placed onto the stack. Moreover, thin contacting members 675 and 676 provide for the minimal deflection of the layer when they move away from the stack. For example, Figure 18G shows how each top layer 677 is deflected by contacting member 675 as it is being placed on stack 678 by the placement member. By providing a thin contacting member, this deflection can be minimized.

In some embodiments, the edges of the cathode layers and anode layers of the battery stack 24 described above are generally co-extensive or aligned with each other within stack 24. In other embodiments, a battery stack can include anode and cathode layers having at least partially offset edges.

For example, Figures 19 and 20 show top and side views of a battery stack 724 according to one embodiment. Battery stack 724 includes an anode layer 701, a separator 702, and a cathode layer 703 that are configured in a layered structure analogous to battery stack 24 described above. The bottom

surface in Figure 19 is the cathode layer, and the top surface is the anode layer with the separator interposed there between. In one embodiment, separator 702 can extend beyond both anode layer 701 and cathode layer 703.

Some cutting and punch-die processes used to make anode and cathode  
5 battery layers can produce burrs on the layers that can result in a short circuit if a burr on an anode layer edge portion makes contact with an adjacent cathode layer or vice-versa. When the dimensions of the cathode and anode layers are the same so that the edges of each layer are aligned, a burr on a cathode layer edge portion can then contact a burr on an anode layer edge portion. Burrs on  
10 overlapping edge portions of the anode and cathode layers may then make contact and cause a short circuit by traversing only half of the thickness of the separator between the two layers.

Accordingly, in one embodiment, the battery stack is constructed with layers having edge portions that are offset from one another. In one  
15 embodiment, this is done by having a cathode layer with a different dimension than the anode layer so that portions of their edges are offset in the layered structure (i.e., either the anode layer or the cathode layer is smaller than the other). The anode and cathode layers may be of the same general shape, for example, but of different surface areas so that the perimeter of one layer is  
20 circumscribed by the perimeter of the other layer.

The capacity of a lithium-based battery is determined by the amount of cathode material (such as  $\text{MnO}_2$ ) that can safely be packaged in the device. Also, it can be desirable to have the anode fully opposed by the cathode. Accordingly, altering the surface area of the anode layer does not appreciably  
25 affect the capacity of the device. Such an arrangement is shown in Figures 19 and 20 where the anode layer 701 is of the same general shape as the cathode layer 703 but with a smaller surface area such that the edge portions of the anode layer are inwardly offset from the cathode layer edges. In this structure, only an edge burr on the anode layer that traverses the entire thickness of the separator  
30 can produce a short circuit. This is in contrast to the case where the edge portions of the two layers are aligned rather than being offset. Offsetting the

edge portions results in a greater tolerance for edge burrs and allows a less constrained manufacturing process and a thinner separator to be used.

Battery stack 724 can include a plurality of electrode elements that are stacked on one another with each electrode element being a layered structure such as shown in Figure 19. The anode layers 701 are stacked on cathode layers 703 in alternate fashion with separator 702 interposed between each anode layer and each cathode layer.

In one embodiment, the offset structure described above can be incorporated into a cylindrical battery. For instance, the anode and cathode layers are cut from a sheet in a desired width and length. The anode layer is made narrower than the cathode layer so that the edges of the anode layer are inwardly offset from the cathode layer edges. The cylinder configuration is then produced by rolling the layers into concentric anode and cathode layers that are separated by separators.

Offsetting of anode layer and cathode layer edge portions may be accomplished by using a variety of differently shaped and/or dimensioned cathode or anode layers.

In one embodiment, for example, a battery used in implantable defibrillators and designed to operate at a rated voltage of approximately 2.75 volts to 3.4 volts, includes a ratio of the anode layer surface area to the cathode layer surface area of approximately 1.2 or greater. In some embodiments, the ratio is approximately 1.3 to approximately 1.4. In various embodiments of the present system, a ratio of Li/MnO<sub>2</sub> capacity can vary between approximately .85 to 1.7.

Referring again to Figure 16, once stack 24 is stacked as shown, the anode sub-assembly layers are interconnected via anode tabs A-D and the cathode sub-assembly layers are interconnected via cathode tabs A-D. The interconnections can be made by welding, staking, or other techniques. Each tab of the various electrode layers is electrically coupled to the other tabs through base manifold layer 100 or 300. Each secondary electrode layer has at least one extension tab positioned to overlay, be co-extensive with, or match with one of the plurality of tab positions A-D.

In this embodiment, the cathode layers are positioned to include four tab groups 350A-350D. Similarly, anode layers are positioned to include four anode tab groups 150A-150D. The tab groups are in electrical contact with each other through the base layer 100 or 300. Thus, each cathode layer is electrically  
5 connected to tab 35 and finally through the feedthrough 36, and each anode layer is connected to tab 37 and then to the case.

In other words, from a top view perspective, anode tabs A-D and cathode tabs A-D are commonly positioned or co-extensive with anode and cathode base tabs A-D respectively.

10 The base tabs and matching secondary tabs may be separate members attached or welded to the metal sheets or the tabs may be integral with the foil layer. The base anodes and cathodes are shown with four tabs and the secondary electrodes are shown with one tab, however, any number of tabs can be provided as needed. In some embodiments, the secondary layers include two or more tabs  
15 to create redundancy.

Again, since the extension tabs are spread out, the size needed to fit the stack within the battery case is reduced. Moreover, the integral interconnects provide for a reduced resistance of the interconnections. This results in an optimized maximal battery surface area per unit volume of the battery.  
20 Moreover, the battery then has reduced impedance due to the integral interconnects. For example, because the battery has an interconnect at each layer, it is in effect a multi-parallel interconnection scheme that has lower impedance than that of a rolled or folded battery with only one or two tabs.

In one embodiment, battery stack 24 includes the matching tabs of each  
25 secondary layer group welded to the corresponding tab of the base layer. These groups are folded against the battery stack, forming the anode tab groups 150A-150D and cathode tab groups 350A-350D. Again, tab groups 350A-350D electrically connect to an external cathode connection via tab 35 which provides an external electrical connection. Tab groups 150A-150D electrically connect to  
30 tab 37.

In this embodiment, tab groups 150A-150D and 350A-350D are folded into position on a top surface 32 of battery stack 24. The tab groups are folded

onto the top of the stack and taped. Alternatively, the tab groups are cut just beyond the weld and taped against a face 30 of the stack (See Figure 21). Each tab group 150A-150D and 350A-350D has a thickness that is less than the sum of the base layer and all the secondary layers.

5           In one example, the thickness of the tab groups are approximately equal to or less than the space between the main body of stack 24 and lid 28 of case 20 (Figure 1). In some embodiments, the space is merely a line-to-line interference fit. The present cathode and anode structure provides that the cathode interconnections and anode interconnections fit within the limited room  
10   available.

For example, in one or more of the embodiments described above the electrode interconnects are spread out or distributed over multiple locations. For example, the cathode or anode layers can be spread out over four locations with four tab groups, with the thickness of each tab group at each location being about  
15   0.006 inch after welding (assuming that four layers at 0.001 inch per layer are at each location). This thinness of the tab group allows the stacked unit to be placed into the housing with the tab groups occupying the space between the housing and the edge of the stack or the clearance space between the lid and the top of the stack. These clearance spaces are allowed for inserting the stack into the  
20   housing. As a comparison, if the cathode tabs were all brought out at one location, the thickness would be greater than 0.015 inch and make it difficult, if not practically impossible, to fold the tabs collectively over the stack as in Figure 21. Thus, this thickness would require that part of the stack be removed or the case enlarged to allow space for routing and connecting the cathode layer  
25   connections, thereby reducing the packing efficiency of the battery.

The embodiment described above show the base layer and secondary layer as cathode and anode layers. However, in some examples only the anode or the cathode layer is arranged in the present fashion and the other is arranged in a different manner.

30           Figure 22A shows front view of stack 24 of Figure 21. Here it can be seen that in one embodiment, the present system allows for the use of non-uniform layers of a battery. In this example, generally designated are a top stack

portion 24A, a middle stack portion 24B and a bottom stack portion 24C. Each of the stack portions 24A-24C includes one or more cathode layers, separator layers, and anode layers. The layers of top portion 24A have at least one dimension which is smaller than the similar layers in middle stack portion 24B.

- 5 Likewise, bottom stack portion 24C includes at least one dimension smaller than similar layers in middle stack portion 24B. This dimensional difference results in the curved profile of stack 24.

Portions 24A-24C are staggered so that their perimeter edges generally (or at least a portion of a side of the stack) define a profile that generally  
10 conforms or is substantially congruent to an adjacent curved interior portion of battery case 20 (Figure 1) without wasting any space within the case. Figure 21 shows that portions 24A-24C can be staggered in two dimensions. As discussed above, fixture 600 (Figure 18) can be used to form the curved or staggered profile stack 24.

- 15 In various embodiments, stack 24 can have a variety of profiles and can be curved along zero, 1, 2, 3, or more sides of the battery. The stack can be curved along a top portion, a bottom portion, or both.

Thus, the curved profile stack allows for a curved profile battery case (Figure 1). This advantageously takes advantage of an implantable medical  
20 device housing, which can include a curved outer surface and a curved inner surface. Thus, the present shape provides an optimal amount of battery power packaged in a way that takes advantage of the preferred shape of an implantable medical device. This allows the battery stack 24 to fit tightly within a curved case with as little wasted space as possible. A curved case is usually a better fit  
25 within an implantable medical device. Thus, this structure allows for a smaller medical device without lowering the available energy of the battery by increasing the volumetric and gravimetric energy density of the battery.

Figure 22B is a perspective view of an insulating sheath or insulating member 50 according to one embodiment and Figure 22C is a side view of  
30 insulating member 50. In this example, insulating member 50 is shaped and dimensioned to hold a battery stack shaped as battery stack 24 (Figures 1 and 21), for example. Other embodiments can shape insulating member 50 as

needed to conform to and cover the outer surfaces of a battery stack. In one embodiment, insulating member 50 is used in place of insulating member 38 (Figure 1) to insulate the battery stack from case 20.

In one embodiment, insulating member 50 includes a main insulating  
5 body 52 which defines a cup shape and includes a top surface 61 and an  
opposing bottom surface 62 and having an opening 54 along a side of the body.  
One or more flaps 55 and 56 extend from an edge of opening 54. Flaps 55 and  
56 are dimensioned to fold over and cover opening 54 after a battery stack has  
been inserted into main body 52. In one embodiment, a first flap portion 57  
10 covers the exposed surface of the battery stack and a second flap portion 58 can  
be attached to the top surface of main body 52. Thus, a battery stack, such as  
stack 24, can be inserted through opening 54 into the hollow area within main  
body 52. Flaps 55 and 56 are folded over the exposed portion of the stack and  
the battery stack is separated from and insulated from the battery case. One or  
15 more gaps or spaces 59 and 60 can be provided between or adjacent to flaps 55  
and 56 to provide room for extension tabs 37 and 35 (Figure 1) to extend from  
the stack.

In one embodiment, flaps 55 and 56 are integrally formed with body 52.  
This integral structure allows for more efficient use of insulating member 50  
20 during manufacturing than a two or more part construction. Integral flaps  
provide for cost savings in both piece part and manufacturing assembly.  
Moreover, the integral structure of insulating member 50 reduces the volumetric  
inefficiencies of two part insulators since the present structure reduces or  
eliminates any overlap region of the insulating structure when it is mounted  
25 around the battery stack. For example, only a single, top seam results when the  
edge of flaps 55 and 56 meet top surface 61.

Figure 23A shows a side view of battery stack 24 and battery case lid 28.  
Feedthrough 36 extends through a feedthrough hole 45 in lid 28 and is connected  
to tab 35. Figure 23B shows a cross-section of the connection. Tab 35 wraps  
30 around feedthrough 36 and is attached at section 35X. This allows for a stress-  
relief area of the tab attachment.

Figure 23C shows a cross-section of the feedthrough assembly 40 of battery 18. Feedthrough assembly 40 includes a ferrule portion 42 integrally fashioned from a wall 43 of lid 28. In other embodiments, the ferrule member can be fashioned from the base 26 of case 20. Ferrule portion 42 includes an  
5 integrally formed annular structure defining feedthrough hole 45 which has an inward facing cylindrical surface 45S. An annular insulating member 44 is located within ferrule portion 42. In one embodiment, annular insulating member 44 can be a glass member, an epoxy member, a ceramic member, or a composite member, for example. In one embodiment, annular member 44  
10 includes a TA23 glass or equivalent glass. Feedthrough post 36 extends through annular member 44. Feedthrough post 36 can include a molybdenum material. Annular member 44 electrically insulates feedthrough 36 from lid 28 and provides a hermetic seal of battery 18.

Annular member 44 has an outer surface abutting inward facing  
15 cylindrical surface 45S. Annular member 44 includes an inner hole 48. Feedthrough post 36 extends through inner hole 48 and is glassed into the battery case. This allows the feedthrough post to have one end connected to a portion of the electrode assembly, such as cathode tab 35, and a second end expose externally to the housing to provide a cathode terminal for the battery. The  
20 integral ferrule structure provides ease of manufacturing a battery since the ferrule does not need to be welded onto the case. Moreover, it can be a cost-effective and size advantageous approach for a hermetically sealed battery. By installing the feedthrough directly into the feedthrough hole in the case, a difficult welding step is eliminated since the case and the feedthrough ferrule are  
25 a combined assembly rather than two separate subassemblies that need to be joined together.

Figure 24A shows a side view of battery 18 after the battery has been assembled. Figure 24B shows a cross-section of battery 18, and Figure 24C shows a close-up detail of the cross-section of Figure 24B. Here it can be seen  
30 that by staggering the tab connections of the present embodiment. A space 60 between stack 24 and lid 28 can be small to allow for an optimal use of space within the battery case.

Figure 25 shows a battery assembly 800 according to one embodiment and Figure 26A shows an exploded view of battery 800. Battery 800 can be constructed using some features and techniques discussed above and the above discussion is incorporated herein by reference. Battery 800 is a flat, stacked  
5 battery having a non-rectangular shape. Again, the techniques described above and below allow the manufacture of almost any arbitrarily shaped battery to allow a designer to fit the battery in a given space within an implantable medical device, for example. A battery stack 814 is mounted within a battery case 802. In one embodiment, case 802 is a two-part clamshell case having a first part 803  
10 and a second part 804. Case 802 can be a metallic case manufactured from a conductive material, such as stainless steel. In another option, case 802 is manufactured using a nonconductive material, such as a ceramic or a plastic.

Battery stack 814 has a region 815 at its periphery which is indented relative to the shape of case 802. This indented region 815 is positioned when  
15 the stack 814 is installed in case 802 to provide space for electrical connections. A feedthrough post 808 passes through case 802 to stack 814 and is electrically insulated from case 802. Feedthrough post 808 is connected to a cathode tab 824, while an anode tab 822 is directly attached to case 802. An anode terminal 810 is connected to the outer surface of case 802. In some embodiments, these  
20 roles are reversed and the cathode tab is connected to the case and the anode tab connects to a feedthrough. In some embodiments, two feedthroughs are provided, one for the anode and one for the cathode. Battery stack 814 is wrapped by a strip of tape 828 to help hold the stack together and in alignment. Stack 814 is covered with one or more insulating members 811 and 812 when  
25 mounted within case 802. In other embodiments, other insulating members, such as the one-piece integral insulating member discussed above can also be used. A backfill port 806 is provided in the case. In one embodiment, an annular insulating member 827 is positioned beneath and around a feedthrough ferrule (see also Figure 47A) to prevent any short circuits between interconnect 824 and  
30 the case. Insulating member 827 also helps minimize galvanic corrosion potential. One example material for member 827 is a polyethylene material.

First part 803 of clamshell case 802 includes a lip 825 which is indented to allow edge 826 of second part 804 to matingly mount around lip 825.

Battery stack 814 is constructed to provide optimal power storage in a small space. This allows battery 800 to be dimensioned to fit within an  
5 implantable medical device, for example, and take up as little volume within the device as possible. In one embodiment, stack 814 includes a plurality of alternating anode and cathode layers separated by separators. As will be detailed below, these alternating electrode layers are stacked, aligned, and interconnected to allow for maximal electrode area in a minimal volume with no wasted space.

10 In one embodiment, stack 814 can include one or more staggered portions or profiles. For example, stack 814 can include non-uniform anode or cathode layers. Stack 814 includes a top portion 820, a middle portion 818 and a bottom portion 816. Each of the stack portions 816-820 includes one or more cathode layers, separator layers, and anode layers. In one embodiment, the layers  
15 of top portion 820 have at least one dimension which is smaller than the similar layers in middle stack portion 818. Likewise, bottom stack portion 816 includes at least one dimension smaller than similar layers in middle stack portion 818. This dimensional difference results in the curved profile of stack 814.

Portions 816-820 are staggered so that their perimeter edges generally (or  
20 at least a portion of side of the stack) define a profile that generally conforms or is substantially congruent to an adjacent curved interior portion of battery case 802. In various embodiments, stack 814 can have a variety of profiles and can be curved along zero, 1, 2, 3, or more sides of the battery. The stack can be curved along a top portion, a bottom portion, or both.

25 Thus, the curved profile stack 814 allows for a curved profile battery case 802. This takes advantage of an implantable medical device housing, which can include a curved outer surface and a curved inner surface. Thus, the present shape provides an optimal amount of battery power packaged in a way which takes advantage of the preferred shape of an implantable medical device. This  
30 allows the battery stack 814 to fit tightly within a curved case with as little wasted space as possible. A curved case is usually a better fit within an implantable medical device. Thus, this structure allows for a smaller medical

device with out lowering the power of the battery. (See Figure 22A and accompanying discussion for other details).

Figure 26B shows battery stack 814 according to one embodiment. In this example, insulating members 811 and 812 (Figure 26A) are omitted and  
5 stack 814 is insulated by wrapping the peripheral edge of the stack with an insulating member such as an insulating strip 811B. In one embodiment, strip 811B includes a strip of polyimide tape wrapped twice around the edge of the stack. Two wraps provides for increased heat resistance along the weld line of the battery case 803, 804 (Figure 26A) and the ability to manage variations in the  
10 height of the battery stack. In this example, the top and bottom surfaces of stack 814 do not need to be insulated from the battery case because they are the same electrical potential as the case. This design also improves the packaging density of battery 802.

Figure 27 shows an exploded view of battery stack 814 according to one  
15 embodiment. Battery stack 814 includes an anode assembly including a plurality of anode sub-assemblies 840, 842, and 844 and a cathode assembly including a plurality of cathode sub-assemblies 841 and 843. Anode sub-assemblies 840 and 844, located near the top and bottom of stack 814, are smaller than the other anode assemblies, and cathode sub-assemblies 841 are smaller than the other  
20 cathode sub-assemblies to accommodate a curved battery case edge. In this example, anodes 840 and 844 have lithium attached to a single side of the anode. Each anode sub-assembly includes a tab extending from the body of the anode at a location A. Each cathode sub-assembly includes a tab extending from the body of the cathode at a location B. To form stack 814, a stacking fixture such as  
25 those discussed above can be used, such as fixtures 600 or 670, for example. After stacking, the anode tabs are brought together and welded to connect each of the anode layers into an anode assembly. Likewise all of the cathode tabs are brought together and welded to form a cathode assembly.

In some embodiments, the anode and cathode layers of stack 814 are  
30 separated by separator as discussed above. In other embodiments, each of the cathode sub-assemblies 841 and 843 includes a heat-sealed separator 846 which is formed to substantially surround, encapsulate, or envelop the cathode member

of the sub-assembly while allowing the extension tab of the cathode to be open.

Figure 28, 29, 30, and 31 show one embodiment of an encapsulated cathode assembly 843. (The present encapsulation technique is also applicable to the anodes discussed herein.) Figure 28 shows a top view of cathode sub-assembly 843 which includes a cathode 853 sandwiched between two layers of separator material 847 with one layer of separator material on either side of the cathode. In one embodiment the separator material is polyethylene, such as Tonen<sup>TM</sup>, or a trilayer (polypropylene, polyethylene, polypropylene) separator material such as Celgard<sup>TM</sup> 2325.

To form the encapsulated cathode assembly 843, the region periphery 848, just outside the outer edge of the cathode is sealed to attach the two layers of the separator 847 together and thus encapsulate the cathode 853 between the separators 847. One technique of sealing the layers includes heat sealing. This can include a thin line heat sealed around the entire periphery as shown as region 848 in Figure 28. In this example, the entire periphery of the cathode is encapsulated within the separator envelope except for the lead 849. In one example, the heat sealing process also cuts the sealed cathode sub-assembly 843 from the web. In some embodiments, the encapsulation process includes ultrasonic welding, ultrasonic sealing, hot die sealing, or inductive sealing the separators together along the periphery of the cathode to form the encapsulated cathode sub-assembly.

When encapsulated, cathode 853 is constrained within the separator envelope-like structure such that cathode 853 does not shift when sub-assembly 843 is grabbed by the separator material 847. This saves time in manufacturing. For example, instead of stacking and carefully aligning an anode, a separator, and a cathode, the stacking operation includes stacking and aligning an anode and an encapsulated cathode assembly 843. This saves manufacturing time and makes alignment simpler since each separator does not have to be aligned with each anode and each cathode since the separator is automatically aligned during the encapsulation process. In other words, it cuts the number of individual pieces to be stacked in half.

Figure 30 shows a detail of the tab portion of the encapsulated cathode sub-assembly 843. The cathode 853 include a base layer 851 having cathode material 852 pressed or otherwise mounted onto one or both sides of the base layer. The two separator layers 847 are sealed at region 850 with tab 849  
5 extending from the sealed region.

Figure 31 shows a detail of a bottom portion of the encapsulated cathode sub-assembly 843. The sealed region 848 of separator layers 847 forms a flange 851 around the periphery of the encapsulated assembly 843. Flange 847, which extends around the periphery of the cathode sub-assembly (See Figure 28), offers  
10 shorting protection around the entire periphery of the cathode rather than just the main surfaces of the cathode as when a single separator layer is placed between each cathode and each anode layer. Moreover, the encapsulated structure prevents any flaking cathode material from floating around the cell once constructed.

15 In one embodiment, stack 814 is formed using the anodes and cathodes shown in Figures 32-33. Figures 32-36 show a cathode and anode interconnection technique according to one embodiment. Figure 32 shows a cathode 860 having a cathode material 861 mounted upon a base layer and an uncoated connection portion or tab portion 862 having a proximal portion 863  
20 connected to the main body of cathode 860 and a distal portion 864 extending therefrom. Figure 33 shows an anode 865 having an anode material 866 mounted upon a base layer and an uncoated connection portion or tab portion 867 having a proximal portion 868 connected to the main body of anode 865 and a distal portion 869 extending therefrom. In one embodiment, connection  
25 members 862 and 867 include one or more separate members attached to the anode or cathode by welding, staking, or other connection method. In other embodiments, connection members 862 and 867 can be integral portions of the anode or the cathode, and can be punched, laser-cut, or otherwise shaped from the base layers.

30 In one embodiment, an additional layer of material is provided on either or both of connection members 862 and 867 to give them a thickness approximately equal to or slightly larger than the thickness of either cathode 860

or anode 865. This extra material minimizes the movement of the connection members when they are squeezed together. A similar structure is discussed below for Figure 36B, the discussion of which is incorporated herein by reference.

5           Figure 34 shows a separator according to one embodiment. Separator 870 includes a cut-out region 873 which allows the connection members 862 and 867 to extend beyond the separator. In some embodiments, a discrete separator is omitted and cathode 860 can be encapsulated within a separator envelop or bag, such as discussed above.

10           Figure 35 shows a top view of a battery stack 871 including alternating layers of anodes 865, separators 870 and cathodes 860. In stack 871, connection members 862 and 867 are overlaying and underlying each other. As used herein, overlay and underlay refer to the position or location of portions of the cathodes and anodes which are commonly positioned from a top view. In the embodiment  
15 of Figure 35, it is seen that connection members 862 and 867 have some commonly positioned portions relative to each other and some portions which are exclusively positioned relative to each other.

For instance, proximal sections 868 and 863 are exclusively positioned or located. This means that at least a portion of proximal sections 868 and 863 do  
20 not overlay or underlay a portion of the proximal sections of the other proximal section. Conversely, distal sections 864 and 869 are commonly positioned and each include at least a portion overlaying or underlying each another.

When stacked as shown in Figure 35, the edges of distal sections 864 and 869 form a surface 874. This surface 874 provides for ease of edge-welding or  
25 otherwise connecting connection members 862 and 867 together, as will be described below. Other embodiments leave one or more gaps in surface 874 when the anodes and cathodes are stacked.

After being stacked as discussed above, at least portions of connection members 862 and 867 are connected to each other. In one embodiment, distal  
30 sections 864 and 867 are edge-welded all along surface 874. In one embodiment, distal sections 864 and 867 are soldered along surface 874. In some embodiments, portions of distal sections 864 and 867 are staked, swaged,

laser-welded, or connected by an electrically conductive adhesive. In one embodiment, they are spot-welded.

After being connected, portions of connection members 867 and 864 are removed or separated so that proximal sections 863 and 868 are electrically  
5 isolated from each other.

Figure 36A shows a portion of stack 871 after portions of distal sections 864 and 869 have been removed from the stack, forming a separation 872 between anode connection members 867 and cathode connection members 862. Separation 872 in the present embodiment electrically isolates section 862 from  
10 section 867. Proximal sections 863 of each cathode in the stack are still coupled to each other as are proximal sections 868 of each anode in the stack. In various embodiments, separation 872 is formed by laser cutting, punching, and/or tool or machine cutting. In some embodiments, an electrically insulative material is inserted in separation 872.

15 The battery interconnection example of Figures 32-36A can help prevent errors during the manufacturing steps which may cause defects in the battery or decrease the reliability of the battery after it is constructed. It can also help decrease the space of the interconnections within the battery, which can be important if the battery is used in an application such as an implantable medical  
20 device. This simple interconnection technique allows interconnections to be made with as few steps as possible.

Figures 36B, 36C, and 36D show a cathode 843B according to one embodiment. In this example, cathode 843B includes a connection tab 844B extending from the main body of the cathode. Figure 36C shows a side view of  
25 cathode 843B. Figure 36D shows a detail of connection tab 844B. Connection tab 844B includes one or more additional layers of a conductive material 845B on each side of a base layer 848B. Material 845B is thick enough to make connection tab 844B approximately as thick as the cathode itself including base layer 848B and a cathode material 847B. Thus, a stack of cathodes such as  
30 cathode 843B results in the cathode tabs of adjacent cathodes being generally flush with each other. A neck area 846B is provided to allow room for the heat

sealed separator, as discussed above. Moreover, neck area 846B also allows for flexibility in the joint to take up manufacturing tolerance variations.

Figure 36E shows a portion of a battery 849B having a battery stack 850B constructed using cathodes 843B and similarly configured anodes 851B having thicker connection tabs 860B, which can be constructed by using additional material on one or both sides of the anode base layer. In one embodiment, cathodes 843B are constructed of a paste cathode material as described above. In some respects, stack 850B is similar to stack 814 discussed above and the above discussion is incorporated herein by reference. Stack 850B allows for the cathode connection members 843B to be connected by edge welding, a spot weld, staking, laser welding, etc. Likewise, the anode connection members 851B are connected together. Again, the thicker tab structure of the connections members 843B and 851B allows for the interconnections to be made without having to squeeze the tabs together, which may damage the structure.

Figures 37-40 show a battery stack 884 constructed according to one embodiment. Battery stack 884 includes some features as discussed above for battery stack 24 shown and discussed in Figures 2-14, and the above discussion is incorporated herein by reference.

Figure 37 shows a base cathode layer 880 having a terminal tab 881 and one or more legs or extensions A, B, and C. Figure 38 shows a base cathode layer 882 having a terminal tab 883. And one or more legs or extensions D, E, and F.

Figure 39 shows battery stack 884 having a sequential stack of alternating cathode layers and anode layers separated by a separator. Stack 884 includes base cathode layer 880 and a plurality of cathode layers which include a tab located in either the A, B, or C position. Likewise, stack 884 includes base anode layer 882 and a plurality of anode layers which each include a tab located in either the D, E, or F position.

Figure 40 shows stack 884 after the respective tabs have been connected together and wrapped around the stack. As noted above, by spreading the cathode and anode interconnections out over separate areas, the overall thickness

required by the interconnections is lessened and less space is needed between stack 884 and the battery case. Terminal tabs 883 and 884 are then attachable to a feedthrough or the case, as discussed above.

After being stacked, any of the battery stacks described above can be  
5 taped around the outer surface of the stack to hold the stack in strict alignment. For example, stack 814 includes a tape 828.

Figure 41 shows a taping fixture 890 according to one embodiment. Taping fixture 890 includes a tape dispenser 891 that holds a roll of tape 892. Taping fixture 890 includes a stack holding fixture 893 which includes a stack  
10 holding member 894. A rotating member 895 is operatively coupled to stack holding member 894 and rotates the stack around a first axis 896. In one example, the first axis is along the long axis of the battery stack. Rotating member 895 can include a manual or motor-operated crank. An indexing member 898 can be used to index and measure the amount of rotation of the  
15 rotating member 895.

Either one or both of dispenser 891 and fixture 893 are rotatable around a second, vertical axis 899 so that the two members 891 and 893 are rotatable relative to each other around the second axis 899. Second axis 899 is approximately perpendicular to first axis 896, and generally vertical relative to  
20 the work surface. In one example, second axis 899 approximately intersects first axis 896.

Figure 42 shows a top view of fixture 890. As tape 892 comes off of tape dispenser 891, the tape forms an angle relative to stack 897. By rotating the stack or dispenser about second axis 899, the angle of the tape relative to the  
25 stack can be varied.

Figures 43A and 43B show one example of a taping process. In use, tape 892 is applied to a first surface 897A of stack 897. The stack is then rotated along axis 896. When the tape strip 892 comes to the edge of the stack 897, the tape dispensing location swings on an arc about axis 899 to match the angle of  
30 the first strip relative to the tangent line of the edge profile and the stack continues to rotate around axis 896.

For example, strip 892 starts out as section 1 across surface 897A of stack 897. In this example, section 1 has an approximately 10 degree angle relative to a perpendicular line of the edge of the stack, which in this example is the tangent line of the edge. When the tape strip reaches the edge of the stack, the dispenser is rotated relative to the stack such that the strip is positioned along side 897B oriented as section 2 (Figure 43B) which is approximately 10 degrees on the other side of the perpendicular from strip 1. Thus there is a 20 degree angle between the two strips with approximately 10 degrees on each side of a perpendicular line to the tangent line. When the stack is then rotated enough along axis 896 such that the tape reaches the edge of the stack, the dispenser is rotated relative to the stack such that the strip then is oriented along section 3 (Figure 43A). This process can be continued through 2, 3, 4, or more rotations.

As can be seen by the dotted lines showing strip 2 in Figure 43A, the tape's orientation is changed as it rounds each edge so that each side is the matching angle of the other side relative to the perpendicular of the tangent line of the edge. For example, a tangent line 893 is shown at the edge between strips 2 and 3. The angles of strips 2 and 3 are approximately equal relative to this tangent line. This technique helps eliminate bunching of the tape at the edges. Moreover, this simple and elegant solution provides for ease of taping and manufacturing battery stack having non-standard, non-rectangular shapes.

Figure 44A and 44B show another example wrapping in accordance with one embodiment. In this example, the tape strip is started at approximately 10 degrees off the perpendicular. Strip 2 is applied approximately 10 degrees on the other side of the perpendicular. (Figure 44B). Strips 3 and 4 are likewise oriented as described above.

In general, the degree of rotation of the dispenser relative to the stack is dependent on the shape of the stack. This system is general in that it can wrap almost any shape stack. Again, this is helpful for use on complex, or oddly shaped stacks. Moreover, fixture 890 allows a stack 897 to be taped in a fixture having only two rotational axes. This simple fixture allows taping of a stack having an arbitrarily complex geometry in a single piece, multi-pass, taping operation.

Due to the complex geometry on the outer profile of the stack, a simple tape operation can be difficult. This system simplifies the equipment needed to dispense and apply a single continuous piece of tape around the stack and to make multiple wraps without requiring many axes of motion.

5 Referring again to the general configuration of battery 800 shown in Figures 25 and 26, Figure 45 shows further details of battery 800 according to one embodiment. Stack 814 is shown inserted in case 802 with a portion of case half 804 shown in broken form. The anode layer subassemblies of stack 814 have their tabs or extension members 817 brought together and interconnected.  
10 A tab 822 is then attached to the anodes by welding, for example, and attached directly to case 802, by welding, for example. The extension members or tabs 819 of the cathode sub-assemblies are brought together and interconnected and a connection member 824 is connected to the cathode tabs. Feedthrough post 808 is connected to tab 824 and extends through a feedthrough hole 809 in the  
15 battery case. The top stack portion 820 is indented relative to middle stack portion 818 to allow for maximum stack size with the curved edge case 802.

Figure 46 shows a top view of a portion of battery 800. Feedthrough post 808 communicates outside the battery by being connected to the cathodes via connection 824. Figure 47A shows a cross-section of Figure 46. In one  
20 embodiment, feedthrough hole 809 is a cylindrical structure integral with case 804. Hole 809 includes an inwardly facing surface defining a ferrule portion 809A. Feedthrough post 808 is electrically insulated from case 804 by annular insulating member 813. In one embodiment, annular insulating member 813 can be a glass member, a ceramic member, an epoxy member, or a composite  
25 member, for example. In one embodiment, annular member 813 includes TA23 glass, or equivalent. Feedthrough post 808 extends through a hole in annular member 813. Feedthrough post 808 can include a molybdenum material. Annular member 813 electrically insulates feedthrough 808 from case 802 and provides a hermetic seal of battery 800.

30 Annular insulating member 813 has an outer surface abutting the inward facing cylindrical surface of ferrule portion 809A. Annular member 813 includes an inner hole that feedthrough post 808 extends through. In one

embodiment, annular member 813 is glassed into the battery case. The integral ferrule structure of this embodiment provides ease of manufacturing a battery since the ferrule does not need to be welded onto the case. Moreover, it can be a cost-effective and size advantageous approach for a hermetically sealed battery.

- 5 By installing the feedthrough directly into the case, a difficult welding step is eliminated since the case and the feedthrough ferrule are a combined assembly rather than two separate subassemblies that need to be joined together.

Figure 47B shows a cross-section of Figure 46. Anode terminal 810 is directly attached to case 802 to complete the connection from the anodes through  
10 tab 822 and via case 802 to terminal 810.

Figure 48A shows a terminal 810B according to one embodiment. Terminal 810B includes a base 64 having a surface 66. A main terminal extension 63 extends from one surface of base 64 and a nipple or protrusion 65 extends from opposing surface 66. Terminal 810B can be formed of a metal  
15 such as gold-plated nickel.

Figure 48B shows a side view of terminal 810B being attached to a case 802 in accordance with one embodiment. Case 802 is a metal, such as 304L or 316L SST. A fixture 68 is used to hold terminal 810B. Fixture 68 and case 802 are oppositely charged. For example, fixture 68 can be negatively charged, while  
20 case 802 is positively charged by an electrode 67, or vice versa. Terminal 810B is positioned such that protrusion 65 is facing case 802 and is the closest portion of terminal 810B to the case. As the terminal is brought closer to the case, protrusion 65 concentrates or focuses the electrical field developed between the oppositely charged case and terminal. When the terminal is close enough, a  
25 spark or arc is sent between the protrusion and the case. This spark vaporizes the nipple and welds the terminal to the case. One example uses a HCD125 MicroJoin™ welding machine set at 30-40 watt-sec power level at 5 lb. force with a pulse width at the #4 setting on the machine.

Figure 48C shows a view of terminal 810B after being attached to case  
30 802. The protrusion has vaporized and surface 66 of base 64 is tightly attached to case 802.

In some embodiments, resistance welding can also be used to attach terminal 810B to the case. For example, terminal 810B and the case can be brought in contact and a current is delivered. Protrusion 65 then melts down and collapses and surface 66 and case 802 are tightly attached.

5        Figure 48D shows further details of terminal 810B according to one embodiment. In one embodiment, base 64 includes a chamfered rear surface 64S, for example of approximately 45 degrees. Front surface 66 can have an angle of approximately 3 degrees. In this example, base 64 has a diameter of approximately 0.022 to 0.030 inches and protrusion 65 has a diameter of  
10        approximately 0.005 to 0.008 inches.

After the stack is mounted within the battery case, the case can be welded shut. An electrolyte is filled into the case through a backfill port, for example. The backfill port is then sealed.

Figures 49A-49B shows a technique for mounting a backfill ball plug 41  
15        to a backfill port 901, in accordance with one embodiment. Backfill plug 41 is shown being mounted to a battery case 803. Backfill port 901 in the battery case has been used to fill the battery case with electrolyte. One problem during the mounting of backfill plugs is that the electrolyte can leach out around the plug before the plug is welded to the case. When this fluid leaches out, it makes  
20        welding difficult. The present technique minimizes leaching and allows for a hermetically sealed battery.

In one embodiment, a first welding electrode 902 is adapted to be used as an applicator to force ball 41 into port 901. For example, electrode 902 can be given a rounded tip to match the shape of the backfill plug. In one embodiment,  
25        plug 41 can be a spherical-shaped ball having a diameter slightly larger than port 901 such that there is an interference fit between plug 41 and the walls 901A defining port 901. For example, in one embodiment, plug 41 has a diameter of approximately 0.026 inches and port 901 has a diameter of approximately 0.025 inches. As applicator/electrode 902 forces plug 41 into port 901, a second  
30        welding electrode 903 is applied against case 803. A current develops between electrode 902 and 903 traveling through plug 41 and case 803. This welds the periphery of plug 41 to the case at weld location 905. This welding technique

seals the ball within the port without allowing any leaching of electrolyte through the gap between the ball and the port walls.

In one embodiment, after weld 905 is formed, electrodes 903 and 902 are removed and the battery is sealed. In other embodiments, as shown in Figure 5 49C an optional laser welding step is provided by a laser welder 907 to further seal the upper periphery of the ball-shaped plug 41 to the case.

Figures 50A shows a backfill plug 910 according to one embodiment. Plug 910 is a cap-shaped plug having a top portion 911. In one embodiment, top portion 911 expands outward to cap portion 912 defining a chamfered region 916 10 between top portion 911 and cap portion 912. Plug 910 includes a waist section 913 which expands into a widened section 914 and then a narrowed section 915. In one embodiment widened section 914 is slightly wider than the diameter of backfill port 901. For example, widened section 914 can be approximately 0.026 inches and backfill port 901 can be approximately 0.025 inches in diameter.

15 Figures 50B and 50C shows an example of plug 910 being mounted to backfill port 901. An applicator electrode 917 is adapted to insert and force plug 910 into backfill port 901 in an interference fit. During or after applicator/electrode 917 forces plug 910 into port 901, a second welding electrode 903 is applied against case 803. A current develops between electrodes 20 910 and 903 traveling through plug 910 and case 803. This welds the widened portion 914 of plug 910 to a wall 901A of the case at weld location 919. Again, this technique of welding while forcing seals the plug within the port without allowing any leaching of electrolyte through the gap between the plug and the port walls.

25 In one embodiment, as shown in Figure 50C an optional laser welding step is provided by a laser welder 907 to laser weld the periphery of the cap 912 of plug 910 to the outer surface of case 803. By providing a chamfered region 916, the laser welding step is improved. Figure 50C shows how plug 910 fits within port 901. Cap portion 912 rests against the outer surface of case 803. 30 Waist portion 913 is located inside of and not touching the walls of port 901. In one embodiment, plug 910 is formed from stainless steel.

Figure 50D shows a terminal 810C according to one embodiment.

Terminal 810C is a combination backfill plug/terminal. Terminal 810C includes an elongated terminal portion 63C and a spherical plug portion 41C. Plug portion 41C is dimensioned to interference fit within backfill hole 901. In one  
5 embodiment, terminal 810C can be attached within the backfill hole 901 and be coupled to the case 803 using the techniques discussed above. For example, a welding fixture 902 can be used to bring terminal 810C within the backfill hole 901 and in contact with case 803 as a second welding electrode 903 is brought against the case to weld the spherical ball portion 41C within the hole, as in  
10 Figures 49A-49C. The combination terminal 810C allows for the elimination of separate terminals and fill plugs (such as terminal 810 and plug 41 discussed above). By combining the two members, manufacturing is eased.

Figure 50E shows a terminal 810D according to one embodiment.

Terminal 810D is a combination backfill plug/terminal. Terminal 810D includes  
15 an elongated terminal portion 63D and a plug portion 910D. Plug portion 910D is similar to plug 910 discussed above and the above discussion is incorporated herein by reference. As with terminal 810C, terminal 810D can be attached within the backfill hole of a battery case.

In various embodiments of the techniques and structures of Figures 49A-  
20 49C and 50A-50E, a parallel gap welder can be used to perform the weld. Various embodiments utilize a current of approximately 10 to approximately 45 watt-sec or higher. One embodiment uses a HCD125 MicroJoin™ welder with settings of 30 watt-seconds and 2 lb. force and pulse width at the #4 setting.

Figure 51 shows a method for manufacturing a battery in accordance with  
25 one embodiment. The method of Figure 51 is an example of one embodiment and it is understood that different steps may be omitted, combined, and/or the order changed within the scope of one or more embodiments. Among other steps, method 51 includes assembling an anode subassembly (930A), assembling a cathode subassembly (930B), stacking a plurality of anode and cathode  
30 subassemblies into a battery stack (930C), welding the tabs of each of the anode subassemblies together and welding each of the tabs of each of the cathode subassemblies together and taping the stack (930D), providing a battery case for

holding the stack (930E), insulating the outer surface of the stack and inserting the stack into the case (930F), welding the anodes to the case (930G), welding the cathodes to a feedthrough (930H), assembling the feedthrough assembly including glassing the feedthrough through a feedthrough insulator (930I),  
5 welding the case shut and filling the case with electrolyte (930J), and inserting and welding a backfill plug to the case (930K).

In one embodiment, assembling the anode sub-assembly (930A) can include forming a plurality of discrete anode layers such as the various anodes discussed above. Figure 52 shows a schematic representation of an anode  
10 assembly system 940 according to one embodiment. System 940 includes a first spool 941 holding a roll of metal base anode material, such as an expanded metal, a solid metal, or an etched metal. A pair of spools 942A and 942B provide a layer of lithium on either side or both of the base material. One or more brushes 946A and 946B clean the lithium layers. The lithium is laminated  
15 onto the base layer at a stage 943. A die-cut mechanism 944 cuts the individual anodes, and a robotic system 945 removes them.

Figure 53 shows a schematic system 950 for forming cathode layers according to one embodiment. A first spool 951 holds a base cathode material. A die cut system 952 cuts the layer to a desired shape. A heat seal system 954  
20 can be provided to seal the separators around the cathode. The cathode assembly can then be transferred by a robotic system 953.

Figure 54 shows a schematic representation of a fixture 1960 for forming a cathode in accordance with one embodiment. Fixture 1960 provides a technique to load a predetermined, precise amount of a cathode powder onto a  
25 cathode carrier strip for use in the manufacture of cathode layers of a battery. Fixture 1960 generally includes a pair of dies or clamp members 1961A and 1961B. One or more guide posts 1964 extend from the inner surface of one of the clamp members 1961A and 1961B. The opposing clamp member includes corresponding holes which mate with the guide posts to keep the pair of  
30 members 1961A and 1961B in alignment when they are brought together. Each of the clamp members 1961A and 1961B include a cut out or cavity portion 1969.

A cathode carrier strip 1966 includes a cathode base section 1967 and one or more guide holes 1968. Guide holes 1968 mate with guide posts 1964 to keep the cathode carrier strip 1966 tightly aligned in fixture 1960.

Fixture 1960 includes a pair of punch members or press heads 1962A and 1962B. Each punch member 1962A and 1962B is associated with one of clamp members 1961A or 1961B such that each punch member moves back and forth through cut-out portion 1969.

In use, a preset amount of  $\text{MnO}_2$  matrix material is poured into the cavity in the bottom clamp member 1961B. In one example, the  $\text{MnO}_2$  powder includes a mixture of 90% pure  $\text{MnO}_2$ , 5% powder carbon, and 5% PTFE slurry binder. A flat edge tool is used to spread the  $\text{MnO}_2$  powder evenly in the cavity. The collector strip 1966 is placed in position over the cavity. A shim 1980 is placed onto the collector strip and fastened down to hold in position. A preset amount of  $\text{MnO}_2$  matrix material is poured into the cavity 1981 of the shim. The flat edge tool is used to spread the powder evenly in the shim cavity. Top clamp member 1961A is then positioned over and fastened to the bottom clamp member.

Figure 55 shows a press 1963 applying force to punch members 1962A and 1962B. The fixture 1960 is placed into press 1963 and the press is cycled with several pressures in steps from low pressure to high pressure until the powder is compacted to the desired density. In one embodiment, a pressure of approximately 48,000 psi is used. In one embodiment, a pressure of approximately 16-21 tons per square inch is used.

In one embodiment, fixture 1960 is mounted to a vibrating system which is actuated to vibrate the fixture either after the powder is placed within the cavities. The vibration settles the powder to fill any gaps and makes the powder have a generally uniform density within the fixture.

Since the size of the cavities of the fixture and the density of the cathode powder is known, a precise amount of powder is compacted onto the carrier strip. Battery cathodes that are later punched or removed from the strip then contain precise amounts of the cathode powder and the cathode powder is evenly distributed across the surfaces of the cathode carrier in a uniform density. This

improves the consistency and reliability of the batteries. In one example, the powder has a pressed density of approximately  $2.7 \text{ g/cm}^3$  and the cathode has an overall thickness (including base metal) of approximately 0.0182 inches. Other embodiments an range form approximately  $2.5$  to  $3.2 \text{ g/cm}^3$ .

5           Figure 56 shows a schematic representation of a fixture 960 for forming a cathode in accordance with one embodiment. Fixture 960 provides a technique to load a predetermined, precise amount of a cathode powder onto a cathode carrier strip for use in the manufacture of cathode layers of a battery. Fixture 960 generally includes a pair of clamp members 961A and 961B. One or more  
10          guide posts 964 extend from the inner surface of one of the clamp members 961A and 961B. The opposing clamp member includes corresponding holes which mate with the guide posts to keep the pair of members 961A and 961B in alignment when they are brought together. Each of the clamp members 961A and 961B include a cut out portion 969. When clamp members 961A and 961B  
15          are brought together, cut out portions 969 define a cavity 970.

A cathode carrier strip 966 includes a cathode base section 967 and one or more guide holes 968. Guide holes 968 mate with guide posts 964 to keep the cathode carrier strip 966 tightly aligned in fixture 960 such that cathode base section 967 is located within cavity 970.

20           Fixture 960 includes a pair of punch members or press heads 962A and 962B. Each punch member 962A and 962B is associated with one of clamp members 961A or 961B such that each punch member moves back and forth through cut-out portion 969. A press 963 applies force to punch members 962A and 962B. A punch surface 971A and 971B of each respective member 962A  
25          and 962B is brought close together within cavity 970.

Figure 57 shows an example of carrier strip 966 mounted in a substantially vertical orientation within fixture 960. Members 961A and 961B are clamped together to hold the carrier strip 966 in place. A cathode powder 972, such as an  $\text{MnO}_2$  mixture, is placed or deposited within cavity 970. In one  
30          embodiment cavity 970 has a width of approximately 0.030 to 0.040 inches. In one example, powder 972 includes a mixture of 90% pure  $\text{MnO}_2$ , 5% powder carbon, and 5% PTFE slurry binder.

In one embodiment, fixture 960 is mounted to a vibrating system 974 which is actuated to vibrate the fixture either during or after the powder is placed within cavity 970. The vibration settles the powder to fill any gaps and makes the powder have a generally uniform density within cavity 970. In one  
5 embodiment, a precise amount of powder 972 is placed within cavity 970. The amount of cathode powder can be varied depending on application of the cathode.

After cavity 970 is activated, press 963 is activated and punch members 962A and 962B press the powder into and onto the base carrier 966. In one  
10 embodiment, a 50 ton press 963 is utilized. In one embodiment, a pressure of approximately 48,000 psi is used to press the powder. Another example uses a pressure of approximately 16-21 tons per square inch.

In one embodiment, cathode powder 972 is sieved before it is deposited into the cavity to prevent any larger pieces of the powder to clog up the cavity.  
15 Since the size of cavity 970 and the tap density of the cathode powder is known, a precise amount of powder is compacted onto the carrier strip. Battery cathodes that are later punched or removed from the strip then contain precise amounts of the cathode powder and the cathode powder is evenly distributed across the surfaces of the cathode carrier in a uniform density. This improves the  
20 consistency and reliability of the batteries. In one example, the powder has a pressed density of approximately 2.7 g/cm<sup>3</sup> and the cathode has an overall thickness (including base metal) of approximately 0.0182 inches. Other embodiments an range from approximately 2.5 to 3.2 g/cm<sup>3</sup>.

Figures 58, 59, and 60 show a top, side and front view of a cathode  
25 forming fixture 974 according to one embodiment. Fixture 974 includes base tabs 975 to mount the fixture to a surface. Clamps 976A and 976B hold a carrier strip within the fixture with a guide member 984 to hold the carrier strip and to keep the two halves of fixture 974 in alignment.

A pair of punch heads 977A and 977B each have a punch member 983A  
30 and 983B associated therewith. The area between the punch members 983A and 983B defines the cavity of the fixture. A spring 980 is positioned between each punch head 977A and 977B and its associated punch member 983A and 983B.

A pair of plug members 978A and 978B are located on top of the fixture, and each plug member has a thumbscrew or other retaining member 979 engaged through the plug and into a block member 981 or 982 located below the plug. A guide post 982 provides further alignment between the two halves of the fixture.

5 A bushing 982 can be used around guide post 982.

As noted above, some embodiments use a cathode paste (such as an  $\text{MnO}_2$  paste) which is coated and then rolled or pressed onto one or more sides of a cathode base layer, such as stainless steel strip or a mesh strip. Individual cathodes can be then excised out of the strip. In some examples, the base layer is  
10 at least partially pre-cut or pre-scored into the desired cathode shape.

Referring again to Figure 51, forming a cathode sub-assembly (930B) can include encapsulating each cathode in a separator envelop, as discussed above.

In one embodiment, the present system provides a battery electrode stack having 12 anode sub-assemblies and 11 cathode sub-assemblies (having sealed  
15 separators). The two anode sub-assemblies located on the stack ends are smaller to accommodate a radius case edge. These two end anode sub-assemblies have lithium attached to one side of their base collector plate only. The two outside cathode sub-assembly layers are also smaller in order to accommodate the radius of the case. Each anode and cathode sub-assembly layer includes an extension  
20 tab that extends out of the stack. The extension tabs are welded together when the stack is completed in order to connect the layers to one another. In one example, the extension tabs are welded with three spot welds and the ends of the tabs are clipped. A ribbon tab is welded to the cathode extensions for connecting them to the feedthrough. The cell is insulated and inserted into the case. The  
25 ribbon extension is welded to the feedthrough and the anode extension is welded directly to the case. The case portions are put together and welded around their interface.

Figure 61 illustrates one of the many applications for the battery. For example, one application includes an implantable medical device 990 which  
30 provides therapeutic stimulus to a heart muscle, for instance, a defibrillator or a cardiac resynchronization therapy device (CRTD). The medical device 990 is coupled with a lead system 991. The lead system 991 is implantable in a patient

and electrically contacts strategic portions of a patient's heart. The medical device 990 includes circuitry 992 which can include monitoring circuitry, therapy circuitry, and a capacitor coupled to a battery 993. Circuitry 992 is designed to monitor heart activity through one or more of the leads of the lead system 991. The therapy circuitry can deliver a pulse of energy through one or more of the leads of lead system 991 to the heart, where the medical device 990 operates according to well known and understood principles. The energy of the device are developed by charging up the capacitor by using battery 993.

In addition to implantable defibrillators, the battery can be incorporated into other cardiac rhythm management systems, such as heart pacers, combination pacer-defibrillators, congestive heart failure devices, and drug-delivery devices for diagnosing or treating cardiac arrhythmias. Moreover, the battery can be incorporated also into non-medical applications. One or more teachings of the present discussion can be incorporated into cylindrical batteries.

Figure 62 shows a performance chart of an example battery constructed according to one embodiment. The battery of Figure 62 was constructed having anodes and cathodes having the values shown in Chart A, below, and was formed in the manner of battery stack of Figure 27.

Chart A

Type	Quantity	Area (cm <sup>2</sup> )	Total Area (cm <sup>2</sup> )	Volume (cc)	Active Material Mass (g)	Estimated Capacity (A-h)
Anode-small	2 surfaces (2 anode layers)	7.526	15.05	0.1147	0.0612	0.236
Anode-large	20surfaces (10 anode layers)	8.013	160.26	1.2211	0.652	2.517
Total		15.539	175.31	1.3358	0.7132	2.753
Cathode-small	4 surfaces (2 cathode layers)	7.796	31.184	0.6812	1.6552	0.3724

Cathode - large	18surfaces (9 cathode layers)	8.29	149.22	3.2596	7.9207	1.7821
Total		16.086	180.404	3.9407	9.576	2.1546
Ratio Li/MnO <sub>2</sub>	1.278					
Cathode current density	0.017 a/cm <sup>2</sup>					

10 A total of 12 lithium anodes were used, with the anodes on each end of  
 the stack only having one surface with lithium and having a smaller area than the  
 other anodes. The chart indicates that the two end anodes each provide one  
 anode surface with the remainder of the anodes providing two anode surfaces  
 each. A total of 11 MnO<sub>2</sub> cathodes were used, with the end two cathodes being  
 15 of smaller surface area. All the cathodes had both surfaces having MnO<sub>2</sub>, so the  
 chart indicates four small cathode surfaces and 18 large cathode surfaces. The  
 cathodes were prepared using a precisely measured amount of cathode powder  
 pressed into the base layer, as discussed above.

After being pressed, the cathodes were heat-sealed between two  
 20 separators, as discusses above. The anodes and cathodes were then alternatingly  
 stacked using the fixture of Figure 18B. The stack was then taped using the  
 fixture of Figure 41. The outer periphery of the stack was then taped by a double  
 wrapping of an insulative tape as in Figure 26B. The anode and cathode  
 extension tabs were brought together and welded. The cathode tabs were  
 25 connected to the feedthrough and the anode tabs were connected to the case. The  
 case portions were put together and welded around their interface. The battery  
 was filled with electrolyte and sealed using techniques discussed above.

The battery of chart A and Figure 62 was designed for an implantable  
 medical device, such as a defibrillator. The battery was designed to have a  
 30 capacity of approximately 2.0 amp-hours with a life span of 6 to 7 years and a  
 peak current level of approximately 3 amps. Using the methods and structures

discussed herein, the battery was constructed to such specifications while having a shape friendly design suitable for fitting into a design space within the defibrillator case and while only having a total volume of  $8.64 \text{ cm}^3$ .

In various embodiments, batteries for different applications can be constructed using various design parameters. For example, some embodiments have a total battery volume of less than approximately  $9.0 \text{ cm}^3$ . Some embodiments have a total battery volume of between approximately  $8.0 \text{ cm}^3$  and  $9.0 \text{ cm}^3$ . Some embodiments have a total battery volume of between approximately  $8.5 \text{ cm}^3$  and  $9.0 \text{ cm}^3$ . Some batteries have a power of approximately 2 to 5 amps and a capacity of approximately 2.0 amp-hours or greater. Other batteries can be manufactured using the techniques herein for different applications. Various embodiments include batteries having sizes ranging from about  $3.0 \text{ cm}^3$  to about  $12 \text{ cm}^3$ . In general, the capacity in amp-hours/ $\text{cm}^3$  of these different size batteries scales up linearly.

Referring again to Figure 62, the charge time A of the battery is seen to be substantially constant over the useful life of the battery. For example, with a 2 - 4 amp current drain, in one embodiment, the charge time is generally about 6 to 7 seconds. Some embodiments have a substantially constant charge time between approximately 5 to 10 seconds. The line C in Figure 62 denotes the open circuit voltage (OCV) of the battery. The line B denotes the Pulse One Average (P1A) of the battery. In one example, the P1A can be used to trigger ERI (elective replacement indicator). This triggers a 3 month clock until EOL (end of life). In the present example, EOL is approximately when OCV reaches 2.75 volts or when P1A reaches 1.75 volts.

The battery of Figure 62 can also be constructed using a paste cathode construction, as discussed above. Moreover, the other anode and cathode interconnection techniques discussed above can also be used to construct a battery of the desired characteristics.

In one or more embodiments, the above described methods and structures provide for a battery making efficient use of space within the case, increased electrode surface area and increased capacity for a battery of a given set of dimensions. In one example, variation in the outer dimensions of one battery

stack to another battery stack is reduced because each is formed of a precisely aligned series of electrode layers. Dimensional variations in the battery stack resulting from variation in the reference points from case to case or alignment apparatus to alignment apparatus can be reduced or eliminated. This provides  
5 improved dimensional consistency in production and allows for reduced tolerances between the battery stack and the battery case. This allows for more efficient use of space internal to the battery case.

In one or more embodiments, different battery chemistries can be used for the cathode structures discussed above. For example, silver vanadium oxide  
10 (SVO), carbon monofluoride ( $\text{Cfx}$ ), and carbon vanadium (CVO) can be utilized in accordance with some embodiments. In addition to primary batteries, batteries according to some embodiments can be formed as secondary type batteries or rechargeable batteries such as Lithium ion.

It is to be understood that the above description is intended to be  
15 illustrative, and not restrictive. Many other embodiments will be apparent to those of skill in the art upon reading and understanding the above description. It should be noted that embodiments discussed in different portions of the description or referred to in different drawings can be combined to form additional embodiments of the present invention. The scope of the invention  
20 should, therefore, be determined with reference to the appended claims, along with the full scope of equivalents to which such claims are entitled.

What is claimed is:

1. A battery stack comprising:  
a plurality of alternating anode and cathode layers, each of the cathode  
5 layers having a base layer and a cathode material layer attached to the base layer,  
the base layer including a cathode tab extending from a first position, each  
cathode tab having a thickness greater than a thickness of the cathode base layer;  
and  
wherein each anode layer includes an anode tab extending from a second  
10 position.
2. The battery stack of claim 1, wherein each anode layer includes a base  
material layer and wherein each anode tab has a thickness greater than a  
thickness of the anode base material layer.  
15
3. The battery stack of claim 1, wherein each of the anode and cathode  
layers includes a substantially non-rectangular shape.
4. The battery stack of claim 1, wherein the cathode material layer includes  
20  $\text{MnO}_2$ .
5. A battery stack comprising:  
a plurality of alternating anode and cathode layers, each of the anode  
layers having a base layer, the anode layer including an anode tab extending from  
25 a first position, the anode tab having a thickness greater than a thickness of the  
anode base layer; and  
wherein each cathode layer includes a cathode tab extending from a  
second position.
6. The battery stack of claim 5, wherein each of the anode and cathode  
30 layers includes a substantially non-rectangular shape.

7. The battery stack of claim 5, wherein the cathode material layer includes  $\text{MnO}_2$ .
8. A battery stack comprising:
- 5 a first electrode layer including a first tab extending from a first position and a second tab extending from a second position; and
- a second electrode layer including a tab, wherein the second electrode layer tab overlays the first tab when the second electrode layer is positioned over the first electrode layer.
- 10
9. The battery stack of claim 8, further comprising a third electrode layer having a tab, wherein the third electrode layer tab overlays the second tab when the third electrode layer is positioned over the first base electrode layer.
- 15 10. The battery stack of claim 8, wherein the first electrode layer includes a third tab extending from a third position, wherein the first tab, the second tab, and the third tab are electrically connected.
11. The battery stack of claim 10, further comprising a fourth electrode layer
- 20 including a tab, wherein the fourth electrode layer tab overlays the third tab when the fourth electrode layer is positioned over the first base electrode layer.
12. The battery stack of claim 8, wherein the first electrode layer and the second electrode layers are cathode electrode layers.
- 25
13. The battery stack of claim 8, wherein the first electrode layer and the second electrode layers are anode electrode layers.
14. The battery stack of claim 8, further comprising a third electrode layer
- 30 including a tab, wherein the third electrode layer tab overlays the second tab when the third electrode layer is positioned over the first base electrode layer,

and wherein at least one of the second electrode layer or the third electrode layer has fewer tabs than the first base electrode layer.

15. The battery stack of claim 8, further comprising a third electrode layer  
5 including a tab, wherein the third electrode layer tab overlays the second tab when the third electrode layer is positioned over the first base electrode layer, wherein the second electrode layer tab and the first tab are connected together to form a first tab group and the third electrode layer tab and the second tab are connected together to form a second tab group, wherein each of the first tab  
10 group and the second tab group has a thickness less than the thickness of the sum of the first tab group and the second tab group.

16. A battery comprising:  
a base cathode electrode layer having two or more tabs;  
15 a base anode electrode layer having two or more tabs;  
a secondary cathode electrode layer having fewer tabs than the base cathode electrode layer; and  
a secondary anode electrode layer having fewer tabs than the base anode electrode layer;  
20 wherein, the secondary cathode electrode layer has at least one tab overlaying and coupled to one of the two or more tabs of the base cathode electrode layer and the secondary anode electrode layer has at least one tab overlaying and coupled to one of the two or more tabs of the base anode electrode layer.

25

17. The battery of claim 16, wherein the base cathode electrode layer includes a tab for connecting to a battery terminal.

18. The battery of claim 16, wherein the base cathode electrode layer  
30 includes a metal sheet having a manganese dioxide ( $\text{MnO}_2$ ) layer attached to a surface of the metal sheet.

19. The battery of claim 18, wherein the  $\text{MnO}_2$  layer does not cover the two or more tabs of the base cathode electrode layer.
20. The battery of claim 16, wherein the base anode electrode layer includes  
5 a metal sheet including a lithium layer.
21. The battery of claim 20, wherein the lithium layer does not cover the two or more tabs of the base anode electrode layer.
- 10 22. A method of forming a battery stack having a plurality of electrode layers, the method comprising:  
attaching a separator layer to each electrode layer of a battery stack; and  
placing each electrode layer into a stacking fixture such that an edge of  
the separator layer of each electrode layer abuts a physical alignment element of  
15 the stacking fixture such that each electrode layer is aligned relative to the physical alignment element.
23. The method of claim 22, wherein the edge of each separator layer  
contacts two or more physical alignment elements.
- 20 24. The method of claim 22, wherein abutting a physical alignment element includes abutting two or more vertically oriented posts.
25. The method of claim 22, wherein abutting a physical alignment element  
25 of a stacking fixture includes abutting an inner surface of a battery case.
26. The method of claim 22, wherein placing includes using a controlled robotic arm to place each layer.
- 30 27. The method of claim 22, wherein placing includes manually placing each of the plurality of layers.

28. A method of maintaining alignment of a battery stack which includes a plurality of layers, the method comprising:  
aligning each of the plurality of layers as each layer is being placed on top of a preceding layer of the battery stack; and  
5 continually applying a compression force on the battery stack to hold each of the layers in that layer's aligned position.
29. The method of claim 28, wherein continually applying a compression force includes continually applying a compression force to a top and a bottom  
10 surface of the battery stack.
30. The method of claim 28, wherein aligning includes using a vision alignment system.
- 15 31. A method of forming a battery stack, the method comprising:  
placing a first battery layer onto a base pad which has a continually applied upward force applied to it such that the base pad forces the first battery layer upward while a pair of upper members apply a downward force on one or more top edge surfaces of the first battery layer;  
20 aligning and placing a second battery layer on top of the first battery layer by using a placement member to press a central portion of the second battery layer into a central portion of the first battery layer while one or more top edge surfaces of the second battery layer remain above the pair of upper members;  
moving the pair of upper members so that the one or more top edge  
25 surfaces of the second battery layer fall against a top surface of the first battery layer;  
moving the pair of upper members back so that the pair of upper members are on top of the one or more top edge surfaces of the second battery layer;  
30 removing the placement member; and  
repeatedly aligning and placing a plurality of battery layers onto previously placed battery layers until a battery stack is formed.

32. The method of claim 31, wherein using a placement member includes using a controlled robotic arm to place each battery layer.

33. The method of claim 31, wherein using a placement member includes  
5 using a manually controlled tool.

34. A method of forming a battery stack for a flat battery, the method comprising:  
sequentially placing a plurality of battery layers on top of each other such  
10 that each one of the plurality of battery layers is, in turn, a top layer of a battery stack; and  
continually applying a compression force between a bottom layer of the battery stack and the top layer of the battery stack until each of the plurality of battery layers is placed.

15 35. The method of claim 34, wherein sequentially placing includes using a controlled robotic arm to place each battery layer.

36. The method of claim 34, wherein sequentially placing includes manually  
20 placing each of the plurality of battery layers.

37. The method of claim 34, wherein continually applying a compression force includes alternately employing a placement member and an upper holding member to apply a force on the top layer of the battery stack.

25 38. The method of claim 34, further including aligning each of the plurality of layers while placing the layer on the battery stack.

39. An apparatus for forming a battery stack, the apparatus comprising:  
30 a base pad for holding a stack of individual battery layers; and  
an upper member movable over the stack to hold down each of the individual layer as the layers are placed onto the stack by a placement member;

wherein, the upper member is adapted to move while the placement member holds down each battery layer as each battery layer is placed onto the stack such that the stack is continually held down by either the placement member or the upper member.

5

40. The apparatus of claim 39, wherein the placement member includes a controlled robotic placement arm.

41. The apparatus of claim 39, wherein the placement member includes a  
10 manually manipulated tool.

42. The apparatus of claim 39, wherein the upper member includes a plastic film supported at each end of the film.

15 43. The apparatus of claim 42, wherein the plastic film includes a roll of plastic film which is configured to be indexed to provide a fresh section of plastic film.

44. The apparatus of claim 42, wherein the plastic film has a thickness of  
20 approximately 0.005 inches or less.

45. The apparatus of claim 42, wherein the plastic film has a thickness of approximately 0.001 or less.

25 46. A battery comprising:  
a case having a curved interior surface; and  
a battery stack including:  
a first battery stack portion having an anode layer and a cathode  
layer and having a first edge surface that confronts the curved interior surface of  
30 the case; and

a second battery stack portion having an anode layer and a cathode layer and having a second edge surface that confronts the curved interior surface of the case;

5 wherein the first edge surface is set back from the second edge surface to define a profile generally congruent to a profile of the curved interior surface.

47. The battery of claim 46, wherein the battery includes a third battery stack portion having an anode layer and a cathode layer and having a third edge  
10 surface that confronts the curved interior surface of the case, wherein the third edge surface is set back from the second edge surface.

48. The battery of claim 46, wherein the first and second battery stacks have respective third and fourth edges, wherein the third edge surface is set back from  
15 the fourth edge surface.

49. An implantable medical device comprising the battery of claim 46.

50. A battery comprising:  
20 a plurality of anode layers;  
a plurality of separators; and  
a plurality of cathode layers;  
wherein the battery includes a layered stack structure having alternating anode layers and cathode layers with one or more separators interposed between  
25 each adjacent anode layer and cathode layer, and further wherein an outer perimeter edge surface of at least one of the cathode layers is offset from an outer perimeter edge surface of at least one of the anode layers that is adjacent to the cathode layer.

30 51. The battery of claim 50, wherein the battery includes a flat, stacked battery structure such that the anode layer, the separator, and the cathode layer are in a layered, stacked configuration.

52. The battery of claim 50, wherein the cathode layer includes a MnO<sub>2</sub> material.

53. A battery comprising:

- 5 an anode layer comprising a flat sheet having a first outer perimeter;  
a separator layer; and  
a cathode layer comprising a flat sheet having a second outer perimeter;  
wherein the battery is constructed as a stacked, layered structure with the  
separator interposed between the cathode layer and the anode, and further  
10 wherein the second outer perimeter of the cathode layer is completely offset from  
the first outer perimeter of the anode layer.

54. The battery of claim 53, wherein the cathode layer includes a MnO<sub>2</sub> material.

15

55. A battery comprising:

- a housing having a wall which includes an integrally formed annular  
structure defining a feedthrough hole, the integrally formed annular structure  
including an inward facing cylindrical surface;  
20 an electrode assembly located within the housing and including an anode  
and a cathode;  
a feedthrough post extending through the feedthrough hole; and  
an electrically insulating member having an outer surface abutting the  
inward facing cylindrical surface and an inner hole, wherein the feedthrough post  
25 extends through the inner hole and has one end connected to a portion of the  
electrode assembly and a second end exposed externally to the housing.

56. The battery of claim 55, wherein the housing includes a base portion and  
a lid portion and the feedthrough hole is within the lid portion.

30

57. The battery of claim 55, wherein the electrode assembly includes a plurality of anode sub-assemblies and cathode sub-assemblies arranged in a layered stack.
- 5 58. The battery of claim 55, wherein the electrically insulating member includes a glass member.
59. A battery comprising:  
a housing including a wall having an integrally formed cylindrical surface  
10 extending from the wall and defining a feedthrough hole in the wall;  
an electrode assembly located within the housing and including an anode and a cathode;  
a cylindrical insulating member located within the feedthrough hole and abutting the inner surface of the integrally formed cylindrical surface, the  
15 cylindrical insulating member having a hole; and  
a feedthrough post having a first end connected to the electrode assembly, the feedthrough post extending through the hole of the cylindrical member.
60. The battery of claim 59, wherein the electrode assembly includes a  
20 plurality of anode sub-assemblies and cathode sub-assemblies arranged in a layered stack.
61. The battery of claim 59, wherein the cylindrical insulating member includes a glass member.
- 25
62. An implantable medical device comprising:  
an outer housing;  
a battery within the housing;  
the battery comprising:  
30 a housing defining a chamber; and  
a plurality of electrode layers within the chamber;

wherein, the plurality of electrode layers includes a base electrode layer having a plurality of base tabs and a plurality of secondary electrode layers, each of the plurality of secondary electrode layers having a tab, wherein at least one of the plurality of secondary electrode layers has fewer tabs than the base electrode layer;

wherein, each of the plurality of secondary electrode layers has at least one tab overlaying and coupled to one of the plurality of base tabs.

63. The medical device of claim 62, wherein  
the plurality of secondary electrode layers are arranged in a first layer group, a second layer group, a third layer group, and a fourth layer group;  
the plurality of base tabs comprise a first base tab, a second base tab, a third base tab, and a fourth base tab;  
the first layer group overlays the first base tab forming a first tab group,  
the second layer group overlays the second base tab forming a second tab group,  
the third layer group overlays the third base tab forming a third tab group, and  
the fourth layer group overlays the fourth base tab forming a fourth tab group;  
each tab group having a thickness less than the thickness of the sum of the first tab group, the second tab group, the third tab group, and the fourth tab group.

64. A method of forming a battery, the method comprising:  
providing a plurality of non-rectangularly shaped cathodes, each non-rectangularly shaped cathode having the same approximate shape as the other non-rectangularly shaped cathodes, each cathode having a tab extending from the cathode;  
providing a plurality of non-rectangularly shaped anodes, each non-rectangularly shaped anode having the same approximate shape as the other non-rectangularly shaped anodes and cathodes, each anode having a tab extending from the anode, each anode tab in a different position from each cathode tab;  
stacking the plurality of anodes and cathodes into a battery stack with a separator between each anode and each cathode;

connecting the cathode tabs to each other;  
connecting the anode tabs to each other;  
placing the battery stack into a non-rectangularly shaped battery case  
having approximately the same shape as the anodes and the cathodes; and  
5 connecting the anode tabs and cathode tabs to respective anode and  
cathode terminals.

65. The method of claim 64, wherein preparing the cathodes includes  
pressing an  $\text{MnO}_2$  powder material into a cathode base layer.

10

66. The method of claim 64, wherein preparing the cathodes includes  
attaching an  $\text{MnO}_2$  paste onto a cathode base layer.

67. The method of claim 64, wherein preparing the cathodes includes heat  
15 sealing each cathode in a separator.

68. A battery stack comprising:  
a first cathode layer including a first tab extending from a first position;  
a first anode layer including a second tab extending from a second  
20 position;  
a second cathode layer having a tab, wherein the second cathode layer tab  
overlays the first tab; and  
a second anode layer including a tab, wherein the second anode layer tab  
overlays the second tab;  
25 wherein the first and second cathode layers include a metal sheet having a  
manganese dioxide ( $\text{MnO}_2$ ) layer attached to a surface of the metal sheet.

69. The battery of claim 68, wherein the  $\text{MnO}_2$  layer does not cover the tab of  
the cathode electrode layers.

30

70. The battery of claim 68, wherein the first and second anode layers  
include a metal sheet including a lithium layer.

71. The battery of claim 70, wherein the lithium layer does not cover the tabs of the anode electrode layers.
72. A method of sealing a backfill port of a battery, the method comprising:  
5 fitting a backfill port plug into a hole in a battery case; and  
welding the port plug to the battery case as the port plug is being fitted into the hole.
73. The method of claim 72, wherein the port plug has a larger diameter than  
10 a diameter of the hole in the battery case such that there is an interference fit between the port plug and the hole.
74. The method of claim 72, wherein the port plug includes a spherical ball-  
shape.
- 15 75. The method of claim 72, wherein the port plug includes a cap shape.
76. The method of claim 72, further comprising providing a second, laser  
weld between the plug and the case.
- 20 77. A method of sealing a backfill port of a battery, the method comprising:  
using a first welding electrode to push a backfill port plug into a hole in a  
battery case;  
placing a second electrode against the battery case; and  
25 delivering a welding energy from the first electrode to the second  
electrode to weld the port plug to the battery case.
78. The method of claim 77, wherein the welding energy is delivered while  
the first electrode is pushing the backfill port plug into the hole.
- 30 79. The method of claim 77, wherein the welding energy is delivered after  
the first electrode has pushed the backfill port plug into the hole.

80. The method of claim 77, wherein the backfill port plug is dimensioned to provide an interference fit between the plug and the battery case.

81. The method of claim 77, further comprising providing a second weld  
5 around a head of the plug after the first weld, wherein the second weld is a laser weld.

82. A battery stack comprising:  
an alternating sequence of anodes and cathodes having a separator  
10 between each anode and each cathode, wherein each separator is connected to an adjacent separator to form a substantially sealed pocket around each cathode.

83. The battery stack of claim 82, wherein a tab of each cathode is exposed beyond the substantially sealed pocket.

15

84. The battery stack of claim 82, wherein each cathode includes  $\text{MnO}_2$ .

85. A battery stack comprising an alternating sequence of anodes and cathodes, wherein each cathode has a first separator on one side and a second  
20 separator on a second side, wherein the first separator and the second separator are connected to each other around at least a portion of their edges.

86. The battery stack of claim 85, wherein the first separator and the second separator define a flange at the connection of the first separator and the second  
25 separator, wherein the flange extends beyond an edge of the cathode and encloses the edge of the cathode.

87. The battery stack of claim 85, wherein the connection between the first separator and the second separator includes a heat seal.

30

88. A battery stack comprising an alternating sequence of anodes and cathodes, wherein each anode has a first separator on one side and a second

separator on a second side, wherein the first separator and the second separator are connected to each other around at least a portion of their edges.

89. The battery stack of claim 88, wherein the first separator and the second  
5 separator define a flange at the connection of the first separator and the second separator, wherein the flange extends beyond an edge of the anode and encloses the edge of the anode.

90. The battery stack of claim 88, wherein the connection between the first  
10 separator and the second separator includes a heat seal.

91. A method comprising:  
placing an electrode between first and second separator sheets; and  
attaching the first separator sheet to the second separator sheet along a  
15 periphery of the electrode to substantially enclose the electrode between the first and second separators.

92. The method of claim 91, wherein attaching the first separator sheet to the  
20 second separator sheet includes heat sealing the separator sheets together.

93. The method of claim 91, wherein attaching the first separator sheet to the  
second separator sheet includes ultrasonic welding the separator sheets together.

94. The method of claim 91, wherein attaching the first separator sheet to the  
25 second separator sheet includes hot die sealing the separator sheets together.

95. The method of claim 91, wherein attaching the first separator sheet to the  
second separator sheet includes inductive heat sealing the separator sheets  
together.

30

96. The method of claim 91, wherein the electrode includes a cathode.

97. The method of claim 91, wherein the electrode includes an anode.
98. A method of forming a cathode for a battery, the method comprising:  
mounting a cathode carrier strip into a fixture having a cavity such that at  
5 least a portion of the cathode carrier strip is located within the cavity;  
depositing a cathode powder into the cavity;  
vibrating the fixture; and  
pressing the cathode powder onto the carrier strip.
- 10 99. The method of claim 98, wherein the cathode carrier strip is mounted  
substantially vertically within the cavity.
100. The method of claim 98, further including sieving the cathode powder  
before the cathode powder is deposited into the cavity.
- 15 101. The method of claim 98, wherein pressing the powder onto the carrier  
strip includes pressing at approximately 16-21 tons per square inch.
102. The method of claim 98, wherein a precise, pre-determined amount of  
20 cathode powder is deposited into the cavity.
103. A method of forming a cathode for a battery, the method comprising:  
mounting a cathode carrier strip within a fixture such that the carrier strip  
is oriented substantially vertical within a cavity of the fixture;  
25 depositing a cathode powder into the cavity; and  
pressing the powder onto the carrier strip.
104. The method of claim 103, wherein the cathode powder includes  $\text{MnO}_2$ .
- 30 105. The method of claim 103, wherein pressing the powder onto the carrier  
strip includes driving a pair of opposing press head members towards each other  
on opposing sides of the carrier strip.

106. The method of claim 103, further comprising vibrating the fixture before pressing the powder onto the carrier strip.

107. A method of forming a cathode for a battery, the method comprising:  
5 providing a clamp member having a cavity;  
depositing a cathode powder into the cavity;  
mounting a cathode carrier strip over the cavity;  
placing a shim over the cathode carrier strip, the shim having a cavity;  
depositing a cathode powder into the shim cavity; and  
10 pressing the cathode powder onto the carrier strip.

108. The method of claim 107, wherein the cathode powder includes  $\text{MnO}_2$ .

109. The method of claim 107, wherein a precise, pre-determined amount of  
15 cathode powder is deposited into the clamp member cavity and a precise, pre-determined amount of cathode powder the shim cavity.

110. A method of forming interconnections of a battery stack, the method comprising:  
20 connecting together one or more anode connection members of one or more anodes and one or more cathode connection members of one or more cathodes; and  
electrically isolating the one or more anode foils from the one or more cathode foils.

25 111. The method of claim 110, wherein electrically isolating includes cutting a portion of the anode connection members and the cathode connection members.

112. The method of claim 110, wherein each of the cathode connection  
30 members has a thickness approximately the same as or greater than a thickness of a main body of each of the one or more cathodes.

113. The method of claim 110, wherein each of the anode connection members has a thickness approximately the same as or greater than a thickness of a main body of each of the one or more anodes.

5 114. A method comprising:

positioning an anode connection member having a distal section and a proximal section and a cathode connection member having a distal section and a proximal section so that the distal section of the anode connection member overlays the distal section of the cathode connection member;

10 connecting the anode connection member and the cathode connection member; and

forming a separation in the distal section of the anode connection member and the distal section of the cathode connection member, wherein the proximal section of the anode connection member is electrically isolated from  
15 the proximal section of the cathode connection member.

115. The method of claim 114, wherein connecting the anode connection member and the cathode connection member includes welding a portion of the anode connection member to a portion of the cathode connection member.

20

116. A battery having a battery stack constructed by the method of claim 114.

117. A method comprising:

25 providing a pair of anodes, each anode having an anode connection member having a distal section and a proximal section;

providing a cathode having a cathode connection member having a distal section and a proximal section;

sandwiching the cathode between the pair of anodes and positioning each anode connection member and the cathode connection member so that the distal  
30 section of each anode connection member overlays or underlays the distal section of the cathode connection member, wherein the cathode connection

member has a thickness such that the cathode connection member substantially fills a gap between the anode connection members;

connecting the anode connection members and the cathode connection member; and

- 5        forming a separation in the distal section of the anode connection members and the distal section of the cathode connection member, wherein the proximal section of the anode connection members is electrically isolated from the proximal section of the cathode connection member.

- 10    118.    The method of claim 117, wherein connecting the anode connection member and the cathode connection member includes welding a portion of the anode connection member to a portion of the cathode connection member.

119.    A method comprising:

- 15        providing a pair of cathodes, each cathode having an cathode connection member having a distal section and a proximal section;
- providing an anode having an anode connection member having a distal section and a proximal section;
- sandwiching the anode between the pair of cathodes and positioning each
- 20    cathode connection member and the anode connection member so that the distal section of each cathode connection member overlays or underlays the distal section of the anode connection member, wherein the anode connection member has a thickness such that the anode connection member substantially fills a gap between the cathode connection members;
- 25        connecting the cathode connection members and the anode connection member; and
- forming a separation in the distal section of the cathode connection members and the distal section of the anode connection member, wherein the proximal section of the cathode connection members is electrically isolated from
- 30    the proximal section of the anode connection member.

120. The method of claim 119, wherein connecting the cathode connection member and the anode connection member includes welding a portion of the cathode connection member to a portion of the anode connection member.

5 121. A method of connecting a terminal to a case, the method comprising:  
providing a protrusion extending from a base surface of a metal terminal;  
applying opposite charges between the case and the metal terminal; and  
bringing the terminal towards the case such that the protrusion is facing  
the case until the protrusion melts or vaporizes and the terminal becomes  
10 attached to the case at the base surface of the terminal.

122. The method of claim 121, wherein the metal terminal and the metal case are formed of dissimilar metals.

15 123. The method of claim 121, wherein an electric field develops between the protrusion and the case when the terminal is brought towards the case.

124. A method comprising:  
providing a terminal including a base having a terminal extension  
20 extending from a first surface of the base and a protrusion extending from an  
opposing, second surface of the base;  
applying opposite electrical charges between the terminal and the case;  
and  
bringing the terminal towards the case with the protrusion facing the case  
25 until an arc goes between the protrusion and the case, whereby the terminal is  
welded to the case.

125. The method of claim 124, wherein the terminal is positively charged and the case is negatively charged.

30

126. The method of claim 124, wherein the terminal is negatively charged and the case is positively charged.

127. A method comprising:

providing a terminal including a base having a terminal extension  
extending from a first surface of the base and a protrusion extending from an  
opposing, second surface of the base;

5       applying opposite electrical charges between the terminal and the case;  
and

bringing the terminal towards the case with the protrusion facing the case  
until the protrusion touches the case and melts, whereby the terminal is welded  
to the case.

10

128. The method of claim 127, wherein the terminal is positively charged and  
the case is negatively charged.

129. The method of claim 127, wherein the terminal is negatively charged and  
15 the case is positively charged.

130. A tape applicator for a battery stack, the tape applicator comprising:

a tape dispenser including a strip of tape; and

a battery stack holder located proximate the tape dispenser and adapted to  
20 rotate a battery stack around a first axis such that the strip of tape is applicable to  
a first surface of the stack as the stack rotates around the first axis, wherein the  
tape dispenser and the holder are movable relative to each other around a second  
axis such that the strip of tape can have two or more orientations relative to the  
battery stack.

25

131. The tape applicator of claim 130, wherein the second axis is  
perpendicular to the first axis.

132. The tape applicator of claim 130, wherein the second axis approximately  
30 intersects the first axis.

133. A method comprising:  
applying a strip of tape from a tape dispenser upon a first surface of a battery stack while rotating the battery stack around a first axis;  
rotating the tape dispenser around a second axis which is substantially  
5 perpendicular to the first axis when the strip of tape reaches an edge of the first surface of the battery stack; and  
applying the strip of tape upon a second surface of the battery stack while rotating the battery stack around the first axis.
- 10 134. The method of claim 133, wherein the first axis is a longitudinal axis of the battery stack.
135. The method of claim 133, wherein the second axis approximately intersects the first axis.
- 15 136. The method of claim 133, wherein when the strip of tape reaches the edge of the first surface of the battery stack, the tape dispenser is rotated such that the angle of the strip of tape on the first surface and the angle of the strip of tape on the second surface are substantially equal relative to a tangent line of the  
20 edge of the stack.
137. A battery comprising:  
a battery stack including a plurality of alternating anode and cathode layers; and  
25 a one-piece insulating sheath dimensioned to substantially surround the battery stack, the insulating sheath including an opening for receiving the battery stack within the insulating sheath and an integral flap to at least partially cover the opening when the battery stack is within the insulating sheath.
- 30 138. The battery of claim 137, wherein the insulating sheath includes one or more spaces for extension tabs of the anode and cathode layers to extend through the insulating sheath.

139. The battery of claim 137, wherein the battery is mounted within the insulating sheath, there is a seam on only one side of the insulting sheath.

140. A method of insulating a battery stack from a battery case, the method comprising:

placing a battery stack through an opening in an insulating sheath to position the battery stack within the insulating sheath; and  
folding a flap of the insulating sheath over the opening.

141. The method of claim 140, wherein the flap is integrally connected to the insulating sheath.

142. The method of claim 140, wherein an upper edge of the flap is attached to a surface of the insulating sheath proximate the opening.

15

143. A battery having a power of approximately 2 to 5 amps and a capacity of approximately 2.0 amp-hours or greater, the battery comprising:

an  $\text{MnO}_2$  cathode;

an anode opposing the  $\text{MnO}_2$  cathode; and

20 a battery case holding the  $\text{MnO}_2$  cathode and the anode;

wherein the battery case has a volume of approximately  $9.0 \text{ cm}^3$  or less.

144. The battery of claim 143, wherein the battery case has a volume of approximately  $8.64 \text{ cm}^3$ .

25

145. The battery of claim 143, wherein the battery case has a volume between approximately  $8.0 \text{ cm}^3$  and  $9.0 \text{ cm}^3$ .

146. The battery of claim 143, wherein the battery case has a volume between  
30 approximately  $8.5 \text{ cm}^3$  and  $9.0 \text{ cm}^3$ .

147. The battery of claim 143, wherein the anode includes lithium.

148. The battery of claim 147, wherein the ratio of lithium to  $\text{MnO}_2$  is approximately 1.27.

149. A battery having a power of approximately 2 to 5 amps and a capacity of approximately 2.0 amp-hours or greater, the battery comprising:  
a plurality of alternating discrete anode and cathode layers formed into a stacked structure, wherein each of the cathode layers includes  $\text{MnO}_2$ .

150. The battery of claim 149, wherein each of the anodes includes lithium.

151. A battery having a power of approximately 2 to 5 amps and a capacity of approximately 2.0 amp-hours or greater, the battery comprising:  
an anode and a cathode having a chemical composition capable of providing a substantially constant charge time for the battery.

152. The battery of claim 151, wherein the substantially constant charge time is between approximately 5 to 10 seconds.

153. The battery of claim 151, wherein the substantially constant charge time is between approximately 6 to 7 seconds.

154. The battery of claim 151, wherein the anode and cathode are mounted within a case, the case having a volume of approximately  $9.0 \text{ cm}^3$  or less.

155. The battery of claim 151, wherein the anode and cathode include a battery case holding the  $\text{MnO}_2$  cathode and the anode;  
wherein the battery case has a volume of approximately  $9.0 \text{ cm}^3$  or less.

156. The battery of claim 151, wherein the anode and cathode comprise a plurality of alternating discrete anode and cathode layers formed into a stacked structure.

157. A battery comprising:  
a battery stack;  
a battery case having a backfill hole, wherein the battery stack is located within the battery case; and  
5 a terminal having a first end extending away from the case and a second end mounted within the backfill hole and coupled to the case.
158. The battery of claim 157, wherein the second end of the terminal has a spherical shape.
- 10 159. The battery of claim 157, wherein the second end of the terminal includes a cap-shaped plug.
160. The battery of claim 157, wherein the battery stack includes a plurality of  
15 alternating anode and cathode layers.
161. The battery of claim 157, wherein the second end of the terminal is welded to the battery case to seal the backfill hole.
- 20 162. A battery comprising:  
a battery stack having an outer periphery edge surface; and  
an insulating strip wrapped around the outer periphery edge surface of the battery stack.
- 25 163. The battery of claim 162, wherein the insulating strip is wrapped at least twice around the outer periphery edge surface of the battery stack.
164. The battery of claim 163, wherein the insulating strip includes an overlapping section about half-way up the battery stack.
- 30 165. The battery of claim 162, wherein the insulating strip includes a polyimide tape.

166. The battery of claim 162, wherein the battery stack includes a plurality of anode layers, a plurality of separators, and a plurality of cathode layers, wherein the battery stack includes a layered stack structure having alternating anode layers and cathode layers with one or more separators interposed between each  
5 adjacent anode layer and cathode layer.

167. The battery of claim 166, wherein anode layers, the separators, and the cathode layers of the battery stack have a non-rectangular shape.
